Testimony of Caswell F. Holloway
Deputy Mayor for Operations, City of New York

Before the New York City Council
Committees on Fire and Criminal Justice Services, Public Safety, and Technology in Government

September 27, 2011

Good morning Chairpersons Cabrera, Crowley, Vallone and members of the City Council Committees on Technology, Fire and Criminal Justice Services, and Public Safety. I am Cas Holloway, Deputy Mayor for Operations. Thank you for the opportunity today to testify on New York City's ongoing investment in first responder communications and on the need for federal legislation to establish a broadband network dedicated to public safety. I am joined by members of the New York City Police Department (NYPD), the Fire Department (FDNY), and Department of Information Technology and Telecommunications (DoITT), who will be able to answer specific questions on our public safety communications infrastructure.

As you know, the September 11, 2001 terrorist attacks highlighted critical vulnerabilities in the reliability and interoperability of New York City's first responder emergency communications. Over the last 10 years, the City has invested heavily to address these vulnerabilities, allocating over $258 million of Homeland Security funding to strengthen our communications capabilities for first responders within New York City, and with our regional and federal partners. As a result, our capabilities today are stronger than ever, and we continue to build upon and improve our first responder communications.

As the Council recognizes, however, Federal action on this issue is imperative. The 9/11 Commission urged Congress to enact legislation to provide for the expedited and increased assignment of radio spectrum for public safety purposes. Legislation pending before Congress would do just that, establishing a nationwide, interoperable, wireless broadband network for public safety. The Administration supports the efforts of the Council to focus local and national attention to this vital issue through Resolution 870-A; along with you, we hope that Congress will quickly resolve any issues and pass legislation to achieve this critical public safety initiative.

While Congressional action is important, New York City has made significant strides to address vulnerabilities in our first responders' communications capabilities.

Before reviewing the specific investments that Mayor Bloomberg has made in public-safety communications since the 9-11 terrorist attacks, I want to first explain what is perhaps the most important operational change that the City has made since that terrible day—the adoption of a comprehensive, standardized Citywide Incident Management System (CIMS) that requires the establishment of a co-located, unified command when multiple City agencies respond to an incident. CIMS is based on the National Incident Management System (NIMS), which ensures compatibility in incident command systems in use across the 50 states and with federal agencies. NIMS provides a systematic, proactive approach to guide local and state jurisdictions in the prevention, preparation, response and recovery from terrorist attacks, major disasters, and other emergencies and allows all levels of government to work efficiently and effectively together. Through this structure, first responders can leverage the benefits of face to face communication, which is the most effective way to share information. On 9-11, the NYPD and FDNY, following long-standing operating procedures, established separate operational commands. As a result—and regardless of the radio technology then in use by both agencies—FDNY and NYPD conducted parallel responses, rather than a unified response that can help to ensure the safest and most efficient deployment of resources in an emergency situation.

CIMS establishes clear roles for responder agencies in all types of multi-agency responses, from car accidents to a building collapse. And agency participation goes far beyond NYPD and FDNY—the Departments of Health, Environmental Protection, and Buildings (to name just a few)—frequently have responsibilities in a multi-agency response, from testing air quality to assessing structural stability. For example, just last week a façade collapsed at a building being demolished on 125th street. When I arrived on scene, I immediately went to the unified command location, where FDNY, DOB, and NYPD were coordinating the operation. CIMS is designed to be scalable, facilitating the integration of additional organizations, such as private sector and non-profit entities.

Through my continued work with Police Commissioner Kelly, Fire Commissioner Cassano, and OEM Commissioner Bruno, share the view that implementation of CIMS—and specifically the requirement that a unified command be established at any multi-agency response—is among the most important advances in public safety communications since 9-11.

Moving on to radio and other telecommunications systems, ten years ago, the use of disparate spectrum created interoperability problems between the City's first responders. Today, members of the NYPD can not only talk to members of the FDNY, but also to a broad range of local, regional and Federal agencies as needed – including the MTA, Port Authority of New York and New Jersey, Nassau, Suffolk, and Westchester Counties, as well as about a dozen Federal agencies including the FBI, Department of Homeland Security, and Secret Service. In fact, the Department of Homeland Security's Office of Emergency Communications (DHS OEC) recognized New York City's Interagency Communications Committee (ICC) earlier this month as a best-practice model for how sophisticated and innovative governance structures can enhance emergency communications efforts and support major initiatives within a region/multi-state framework. The ICC, which was created in 2002, is a regional consortium of first responders that bring together over 40 local, state and federal agencies to develop, test and implement interoperable communications strategies. The group worked together to establish the Tactical Interoperable Communications Plan (TICP), which consolidates information across agencies, disciplines and jurisdictions by documenting regional communications capabilities in order to provide a usable and accurate regional tactical incident response tool. The TICP met the federal government's mandate in 2004 and 2006 to achieve interoperability within one hour of an incident, which was tested last summer. The Department of Homeland Security conferred its highest rating on the ICC for the coordinated, multi-agency operational planning and mobilization during the Macy's July 2010 Fireworks Show. During this event, more than 5,000 emergency responders and support personnel from more than fifty governmental and non-governmental agencies in New York and New Jersey worked together using a series of mobile command posts along with Tactical and Joint Emergency Operations Centers to communicate and share information on the ground.

New York City's public safety communications infrastructure is characterized by a complex and sophisticated mix of technologies that support day-to-day, mission critical incident response as well as Citywide and regional joint operations. This infrastructure consists of a variety of land mobile radio (LMR) systems and solutions that include conventional, trunked, and point-to-point systems, along with dispatch consoles, fixed and mobile audio bridges and gateways that operate across VHF, UHF and 800 MHz frequency bands. This infrastructure also supports nearly 85,000 radios used by our public safety and essential service agencies. These agencies also rely on a host of wireless and data applications. Our systems and solutions are constantly improving and allow for reliable and secure communications among first responders on a tactical, operational, and command and control level.

On a tactical level, the NYPD and FDNY primarily depend upon point-to-point radio communications. Even on this basic level, our first responders have interoperable capabilities enabling advanced coordination at the incident scene. For example, officers from the NYPD Emergency Service Unit can communicate with the FDNY Fire Rescue Division to stage and execute joint operations on dedicated tactical channels.

On an operational level, DoITT has completed the design and roll-out of the Citywide Radio Network (CRN), which has consolidated many of the separate frequencies previously used by various New York City agencies, providing expanded coverage and interoperability capabilities. It also provides dedicated frequencies for each borough that can be accessed by multiple City agencies at the same time. As a result, CRN gives agencies the ability to communicate in the same band of frequencies. This increases responder safety, situational awareness and command and control. Through CRN, users are able to receive consistent and reliable communications throughout the five boroughs on the same frequency band regardless of location. This network even allows for unprecedented coverage on New York City's waterways. The FDNY is in the process of fully migrating its fire service and EMS dispatch systems to CRN. This network employs narrowaband conventional and Trunked Radio Technologies, which increases channel efficiency during a major emergency or during periods of peak demand. Using CRN, FDNY Command Center personnel and en-route staff can monitor on-scene voice transmissions in real-time, which assists in remote decision-making.

From a Command and Control perspective, communications are supported on the region's Wide Area Interoperability Network, which is managed by the NYPD. This network has 3 dedicated interoperability channels – two specifically for New York City and one region-wide channel, which can be used to support emergency communications north of the City in Westchester County, east of the City in Nassau and Suffolk counties on Long Island and west of the City to Newark, NJ. The Port Authority and MTA can also operate on the network along with federal agencies who may be responding to an incident in New York City. The NYPD is also working on building out an interoperable simulcast channel at the new World Trade Center site, which will be used by various local, regional and federal entities.

Finally, there is the 800-MHz Trunked Radio Network, which supports both day-to-day and emergency communications for the City's public safety and essential service agencies. Using this system, roll calls are conducted every other day by OEM Watch Command amongst 60 City, state, federal, neighboring public safety and essential service agencies and associated jurisdictions, as well as critical infrastructure/key resource subscribers to ensure that all lines of communication are open and operational. A distinct healthcare and medical facility talk group has also been created on the network to make interoperability possible among the OEM Health Response Unit – a consortium of 87 health care and related facilities. This specialized talk group facilitates the real-time exchange of information concerning the availability of medical services, and enhances the City's overall preparedness level. Finally, more than 50 commissioners from the City's Mayoral agencies participate in a supplementary talk group, so that at the request of the Mayor, agency heads can be quickly reached to disseminate information to executive staff and response teams should other channels of communication be unavailable.

Not only has the City become a model of voice interoperability, but we are leading the nation through the development of our state-of-the-art wireless data network, built exclusively for the use of City agencies. NYCWiN is the most aggressive commitment by any municipality in the United States to provide a next-generation public safety infrastructure and has eliminated many of the challenges of sharing data in the urban environment. It was completed in 2009 and has been providing mission critical video, voice and data communications – through portable, mobile and fixed-location technologies – to the City's first responders and essential public services. By enabling secure transfer of critical information, coordination of mobile resources and automation of labor intensive processes, first responders are able to enhance situational awareness, improve responder safety and enable remote decision making. NYCWiN provides its subscribers 24/7 network support, and features strong encryption, multi-level authentication and physically-protected equipment installations. Nearly 400 sites provide ubiquitous coverage to more than 300 square miles spanning all five boroughs. Today, NYCWiN powers more than 300 applications that span 29 City agencies on nearly 750,000 devices.

First responders in the field rely on NYCWiN for access to real-time vital information such as photos, warrants, license plates, maps, and operating procedures. Additionally, incident commanders depend on the network to enhance coordination with on-scene personnel through the use of data transmission, full-motion video streaming and automatic vehicle location. The NYPD Real Time Crime Center leverages this network infrastructure by enabling officers in the field to access and search their databases through NYCWiN. Another innovative use of NYCWiN is the emergence of the FDNY Electronic Command Board, which coordinates fire service resources in the field. Over NYCWiN, fire-ground radios are keyed up to track firefighters in real-time via mobile modem installations on the apparatus and in battalion chief vehicles.

Further enhancing situational awareness is the City's Operational Video System (OVS), an interoperable video platform. This incident-based video is shared across disparate video systems and links the Mayor's Office, NYPD, FDNY, OEM and other authorized agencies. OVS allows for highly coordinated responses and enhances the safety of first responders by bringing feeds from helicopters, watercraft, mobile command vehicles and other deployable cameras. In one instance, the OVS was mobilized in January 2009 when US Airways flight 1549 landed in the

Hudson River. Within 15 minutes, OVS was streaming video from two first responder vehicles to the FDNY Command Center and the feed was shared with other first responder agencies. All of these innovative investments have significantly improved operational control and incident management of emergencies. But it is not enough.

As we look to the future, our nation's first responders need a nationwide broadband network dedicated specifically to public safety. New York City has been a national leader pushing for this critical tool, which is essential to the mission of first responder agencies around the country. For this reason, as discussed earlier, the Administration supports Resolution 870-A, and has been actively lobbying our leaders in Washington for the creation of a common radio spectrum dedicated to public safety. Past experience has proven that our first responders cannot depend on commercial networks for reliable broadband communications. Time and time again, during emergency incidents, cell phone networks have been overwhelmed, making police and fire communications over them virtually impossible.

Finally, as you may know, this year Congress drastically cut the level of Homeland Security funding directed toward state and local governments for FY12. New York City, which remains the number 1 target for terrorist threats, cannot sustain such an arbitrary reduction in funds to many of the City's critical homeland security programs. I hope that the Council will work with us to urge Congress to restore this vital funding.

New York City has worked hard to ensure that our first responders can operate safely and effectively when responding to an emergency. By demanding the highest standards in reliability and interoperability both for voice and data communications, we have improved significantly over the past decade. This in turn has made all New Yorkers safer.

Thank you again for this opportunity to testify and I am happy to answer any questions you may have.

Testimony
on behalf of the Public Safety Alliance (PSA)

Mr. Yucel Ors
PSA Project Manager & Director of Government Relations
Association of Public-Safety Communications Officials (APCO),
International

New York City Council
Joint Hearing of the Committees on Fire and Criminal Justice Services,
Public Safety, and Technology

September 27, 2011

Mr. Chairman, Ranking Member, and all the members of the Committees, thank you on behalf of the leadership of APCO Intl. (The Association of Public-Safety Communications International (APCO) and the Public Safety Alliance (PSA) for this opportunity to appear before you today regarding Proposed Resolution Number 870-A, which calls for Congress to pass and President Obama to sign into law ***S.911; Public Safety Spectrum and Wireless Innovation Act of 2011***.

APCO International is the world's largest organization of public safety communications professionals. It serves the needs of public safety communications practitioners worldwide—and the welfare of the general public as a whole—by providing complete expertise, professional development, technical assistance, advocacy and outreach to nearly 16,000 members.

The Public Safety Alliance is a partnership with the nation's leading public safety associations, which includes the Association of Public-Safety Communications Officials (APCO) International, the International Association of Chiefs of Police, the International Association of Fire Chiefs, the National Sheriffs' Association, the Major Cities Chiefs Association, the Major County Sheriffs' Association, the Metropolitan Fire Chiefs Association, the National Emergency Management Association and the National Association of State EMS Officials. The purpose of the PSA is to ensure law enforcement, fire and EMS agencies are able to use the most technologically advanced communications capabilities that meets the difficult, life-threatening challenges they face everyday as they protect America. The partnership is operated as a program of APCO International.

As you may know, For over two years now, APCO International and the PSA have worked together tirelessly to ensure that our nation's first responders have the best and most up-to-date tools available to them in the event of another natural or man-made disaster. One of the biggest challenges to the public safety community is a lack of adequate spectrum for first responders to communicate with one another across different counties, states, jurisdictions for day-to-day operations as well as acute emergencies. We believe that the passage of S.911, bipartisan legislation introduced by Senators Kay Bailey Hutchison (R-TX) and John "Jay" Rockefeller, IV (D-WV), holds the key to the safety of all first responders. Since introduction, the bill has garnered overwhelming support in the United States Senate Committee of jurisdiction, the Senate Commerce, Science and Transportation Committee, where Senators Rockefeller and Hutchison serve respectively as Chairman and Ranking Member.

Indeed, in re-introducing legislation at the beginning of this 112th Congress on January 25th – the same day that President Obama and his administration formally announced his support for the allocation of D block to public safety as part of his State of the Union address -- Chairman Rockefeller declared resolution of this issue as the committee's top legislative priority for this year. After working through various issues regarding how to fund and oversee the Public Safety Broadband Data Network (PSBN), Rockefeller and Hutchison developed S.911 as a compromise bill this past spring, where it since has been favorably voted out of committee in June by a margin of 21-4. Among the agreements included in S.911 was dedication of a portion of spectrum auction revenue for deficit reduction of up to $10 billion dollars, as well as providing and $11.75 billion dollars over 10 years for the PSBN. S.911 has awaited floor consideration by the entire US Senate since that time. The sponsors and supporters had hoped for its passage into law before the recent 10 Year Remembrance of the tragic events of 9/11, and continue to actively push for its enactment this year. Indeed, Senate Majority Leader Harry Reid (D-NV), a co-sponsor of Senator Rockefeller's legislation in the closing days of the 111th Congress, had included language from S.911 in his debt deal proposal in August, 2011, but the House Republicans opposed its' inclusion in the final bill.

Led by Senators Charles Schumer and Kirsten Gillibrand, as well as Congressman Peter King (R-NY), as Chairman of the House Homeland Security Committee, the State and City of New York's congressional delegation has been among the strongest supporters and advocates in the nation for legislation to finally adopt one of the last unmet recommendations of the 9/11 Commission, that is, to provide public safety and our first responders with additional spectrum to improve the communications and interoperability of our country's emergency communications for both day-to-day and in times of crisis. Indeed, Congressman King sponsored the first piece of legislation to allocate additional spectrum in response to the 9/11 Report as H.R.5081 in April, 2010 in the 111th Congress. HR5081 acquired more than 80 bipartisan co-sponsors last year. Chairman King and Ranking Member Bennie Thompson (D-MS) reintroduced legislation this year, ***H.R.607; the Broadband for First Responders Act of 2011***, which builds upon HR5081 with the addition of funding and governance language for the PSBN. H.R. 607 currently has 46 co-sponsors and sits before the House committee of jurisdiction, the House Energy and Commerce Committee, awaiting further consideration. Just this past week, Congressman King joined with Representative Steve Rothman (D-NJ) to introduce the 7th bill in the 112th Congress to allocate D block to public safety, provide $7-12 billion dollars in funding derived from other spectrum auctions to finance the build out of the

PSBN, and to establish a governance structure to oversee the build out and sustainment of the nationwide network. Let me specify here that none of these proposals would require any new monies from our nation's taxpayers. It is fully funded with revenue derived from new "incentive" and other spectrum auctions that are widely supported by government, industry and consumer groups to free up additional spectrum to meet the dramatic increase in demand for commercial wireless broadband services throughout our country.

As the 9/11 Co-chairs recently testified to Congress regarding their 9/11 Report Card, "Despite considerable progress since 9/11, some major 9/11 Commission recommendations remain unfulfilled. These remaining recommendations require urgent attention", and chief among them "is the provision of additional spectrum for public safety." The 9/11 Commission co-chairs, former New Jersey Governor Thomas Kean (R-NJ) and former Congressman Lee Hamilton (D-NY), have repeatedly testified before Congress urging "immediate allocation of the D-block spectrum to public safety," stating "We must not approach these urgent matters at a leisurely pace. We don't know when the next attack or disaster will strike. Further delay is intolerable. We urge the Congress to act."

As well, our nation's first Secretary of Homeland Security, former Governor and Congressman Tom Ridge (R-PA), recently spoke at a U.S. Chamber of Commerce Homeland Security event declaring that Congress' inaction regarding D block is a "bloody outrage," stating that "Congress has failed first responders."

Industry has also joined in calling for immediate allocation of D block. Leading technology association, TechAmerica, which is composed of our nation's premiere technology corporations and start-up innovators, held a briefing of congressional staff last week calling on Congress to allocate D block to spur the economy and create jobs. Likewise, the Telecommunications Industry Association (TIA) released a study in late August estimating that 100,000 jobs would be created with the build-out of the Public Safety Broadband Network, and later this week, the 9-1-1 Industry Alliance (9IA) is expected to formally endorse legislation to allocate D block to public safety.

Couple this with the fact that all of our nation's first responders and major national public safety associations – including the International Association of Chiefs of Police (IACP), International Association of Fire Chiefs (IAFC), National Sheriffs' Association (NSA), National Emergency Management Associations (NEMA), National Association of State EMS Officials (NASEMSO), Emergency Nurses Association (ENA), Fraternal Order of Police (FOP), National Association of Police Organizations (NAPO), National Troopers Council (NTC), National Volunteer Fire Council (NVFC), Major City Chiefs Association (MCCA), Major County Sheriffs' Association (MCSA), National Criminal Justice Association (NCJA), Metro Fire Chiefs Association (MFCA), National Association of Attorneys Generals (NAAG), Police Executive Research Forum (PERF), National Organization of Black Law Enforcement Executives (NOBLE), and countless others – have all united in support of allocation of D block with funding of the PSBN. Furthermore, all of the major national associations representing state and local government officials have come out in support, including the National Governors

Association (NGA), the U.S. Conference of Mayors (USCM), the National League of Cities (NLC), Council of State Governments (CSG,) the National Association of State Chief Information Officers (NASCIO), the National Association of State Telecommunications Directors (NASTD), the National Association of Counties (NACO), the International City/County Managers Association (ICMA) and the National Council of State Legislatures (NCSL).

At this time, I would like to submit into the record a comprehensive report that APCO Intl. has painstakingly compiled in recent weeks documenting the large volume of reports, studies, field tests, commentary, testimony and legal filings that have become part of the legislative and regulatory record that, when combined, provide an overwhelming and convincing argument why Congress must act now. This report includes a section-by-section analysis of S.911 and the July, 2011 Congressional Budget Office's (CBO) analysis of the bill's costs and other provisions. I want to highlight that the CBO report finds that the network, once built out, would be self-sustained for its continuing operation, so no further costs are anticipated for the nationwide network once its completed.

At this point, you may be asking, who is opposed and why? And why hasn't Congress already enacted this legislation? The answer is simple, "some in Congress still believe that we cannot afford the cost of allocating spectrum to public safety, or as they phrase it, "give away spectrum to public safety" and are weary of directing significant funding to a network right now because of the current economic and fiscal challenges we face nationally and at the federal level. To this, the answer is just as simple, "We cannot afford to wait anymore." As Congressman Bennie Thompson stated at a hearing on this matter some months ago, "It is no time for Congress to be a penny wise and a pound foolish." With sufficient spectrum allocation and funding, this spectrum and this network will save our nation immeasurable real costs, as well as in lives saved, time and efficiency, in the immediate-to-long term future.

We know that it will cost no more to build out a 20 MHz network than a 10 MHz network today, but it will cost more than twice as much to provide this additional spectrum and network capacity later. The Federal Communications Commission (FCC) has been clear in saying that public safety will need more than 10 MHz of spectrum. A recent study by wireless expert Peter Rysavy and results of a comprehensive field test on one of the first "waiver" deployments of a public safety broadband network in greater San Francisco by public safety wireless specialist Andy Seybold back up this claim. Together they show that 10 MHz of spectrum will not provide enough capacity today to allow public safety to fully utilize existing broadband technologies such as streaming video for effective, mission-critical response to the most common and far too routine incidents, such as large fires and bank robberies.

Over the past two years, the record has become quite clear and convincing. Public safety requires (1) this additional spectrum, the D block, (2) a new, independent national governance structure with sufficient state and local government and public safety representation, and (3) sufficient funding to finally realize a nationwide, mission-critical, and interoperable public safety broadband network for two-way transmission of data, text, video, pictures and other large quantities of information to prevent, mitigate and respond to emergency incidents, both everyday and during major critical incidents, including natural disasters and terrorists threats and attacks.

Therefore, the PSA and APCO International urge you and your colleagues in the strongest possible terms to pass Resolution 870-A; and we call upon you to provide this resolution as a model for your colleagues in cities, counties and states nationwide to emulate in formally adopting and submitting similar resolutions to Congress in the coming days and weeks.

Finally, we understand that the Joint Committee on Deficit Reduction, otherwise known as the Super Committee, which Congress created as part of the recently passed Debt Deal, is actively considering inclusion of spectrum auctions and related spectrum policy within their mandated legislative process. We respectfully request that, upon enactment of Resolution 870-A, these committees and the City of New York's entire City Council direct that a copy of the resolution be provided to every member of the Super Committee, as well as the bipartisan House and Senate leadership that appointed them, along with the bipartisan leadership of the House and Senate committees of jurisdiction. Please tell them that they must finally consider and pass this long overdue legislation to keep America and its first responders safe today, tomorrow and well into the future by providing them with the 21st Century technology and communication tools to do their job.

Thank again for this opportunity to provide testimony on behalf of APCO International and the Public Safety Alliance. I am happy to take any questions that the committees may have at this time.

BUILDING A NATIONWIDE PUBLIC SAFETY BROADBAND NETWORK

Prepared for: New York City Council's Committee on Fire and Criminal Justice Services and the Committee on Public Safety and the Committee on Technology
Prepared by: APCO International Staff
Date: SEPTEMBER 26, 2011

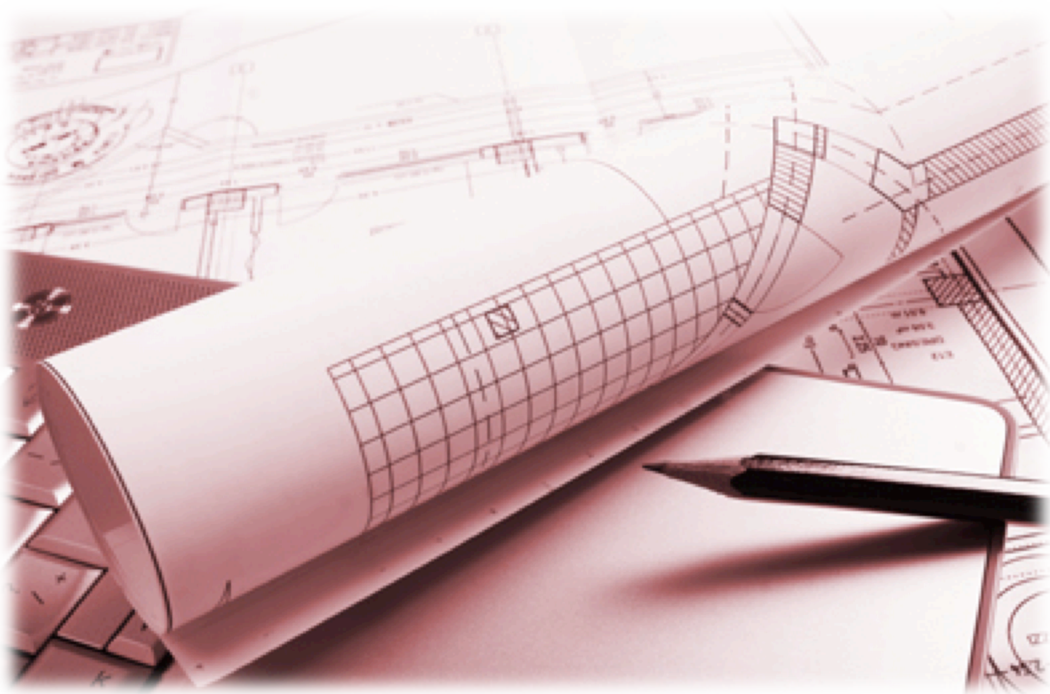

Table of Contents

I. EXECUTIVE SUMMARY

Congress, by its actions, has established spectrum policy as a significant national interest, and that electromagnetic spectrum is a finite and increasingly scarce national resource. They have mandated that the Federal Communications Commission (FCC) and the National Telecommunications and Information Administration (NTIA) within the United States Department of Commerce be vested with the authority and responsibility for the management, oversight and enforcement of spectral policy.

Congress further empowered the FCC with the authority to manage, oversee and enforce state and local government assignment and use of spectrum, as well as commercial assignment and use, and has likewise empowered NTIA with those same authorities with respect to the Federal government's assignment and use of spectrum. Congress also charged the FCC with management and oversight of spectrum auction activities.

Since its inception, the FCC has assigned state and local public safety entities with spectrum as needed, and has consistently utilized a policy of interweaving public safety spectrum with industry and other spectrum licensees in an effort to provide public safety with associated economies of scale based on the landscape of traditional voice-centric, Land Mobile Radio (LMR) technology. Therefore, spectrum assignments were traditionally provided to public safety on an "as needed" basis in small slivers of spectrum from throughout the entire spectrum map. The policy resulted in the current patchwork of spectrum that public safety maintains, which has resulted in multiple disparate networks only partially pieced together through expensive patching technologies. (see Appendix titled APCO: Current Public Safety Spectrum Holdings Report for detailed breakdown of public safety's current spectrum assignments)

With the advent of more advanced emergency communications systems, including cellular and wireless broadband technologies, the spectrum assignment policies of the past has put the public's safety, as well as the entire Nation at risk. Instead of utilizing multiple small slivers of spectrum to communicate through a 6.25 KHz or 12.5 KHz Land Mobile Radio (LMR) channel, current and emerging communications will utilize larger swaths of spectrum, commonly referred to broadband. Additionally, the traditional separation between Federal public safety, first responders and state-local public safety entities in a 21st Century post 9/11 world, have become dramatically less effective when coordinating both a day-to-day emergency response and major events/incidents. This requires the work of both the NTIA and FCC to significantly strengthen their cooperation, spectrum management oversight and policy development and implementation.

In the wake of the Oklahoma City bombing in 1995 - which at the time was the biggest terror attack ever struck on US soil - all of the major national public safety and government associations (referred to as the Big 7) came together with one voice to petition Congress, the Administration and the Nation to allocate 24 MHz of additional spectrum to alleviate the over congestion of then-current traditional, voice-centric LMR systems throughout the nation, and to allow for increased interoperability with new and existing LMR systems. Congress approved the assignment of the 24 MHz in 1997, and it was allocated to public safety from spectrum freed up by broadcasters' analog to digital transition. It was not until June, 2009 -- 12 years later -- that public safety finally obtained full access to utilize this spectrum.

In the intervening years, the attacks of 9/11, Hurricane Katrina, the Columbine school shootings and many other incidents further illustrated the need for additional spectrum, beyond the 24 MHz, to allow public safety and first responders to develop and deploy broadband networks for data and video usage. Meanwhile, the FCC had established a spectrum policy that designated 10 MHz of the 24 MHz provided to state and local public safety for development of a public safety broadband network (assigned to the current Public Safety Broadband Licensee, which is the Public Safety Spectrum Trust). This public safety broadband network was to be coupled with 10 MHz of adjacent spectrum (commonly referred to as the D Block) that would be auctioned with public safety encumbrances, including ruthless preemption, to a commercial provider to establish 20 MHz capacity for public safety through a public-private partnership. The subsequent auction of the D block was scheduled for early 2008 as part of the overall auction of the 700 MHz band. By all accounts the auction of the 700 MHz band was a success and derived $19 billion in revenue for the United States Treasury, even as the Congressional Budget Office's analysis projected a revenue of $12 billion dollars. This estimate of $12 billion included the auction of the D block, which in reality failed to receive a minimum bid and was never auctioned.

Once again in 2009, all major state and local public safety, first responder and Big 7 national associations came together with industry and other supporters in the wake of the failed auction of the D block to unify on a single effort to petition Congress and the Administration to allocate the D block to public safety. The overall goal of the coalition is to allocate the D block to public safety, provide sufficient funding derived from the auction of other spectrum, and the creation of an independent, nationwide governance structure with sufficient state and local government and public safety representation to allow for a Public Safety Broadband Network, consistent with the vision of a public-private partnership.

Many leaders in Washington, as well as those in industry, academia, the public and non-profit sectors, have come to support and champion public safety's top legislative priority in the current and previous Congress. Indeed, after a comprehensive, government-wide analysis of the issue, President Obama and his Administration formally added their support in January 2011 as part of the President's State of Union (SOTU) address, as well as Secretary Napolitano's State of Homeland Security Union and the President's Fiscal Year 2012 Budget submission to Congress.

The first piece of bipartisan legislation, introduced in April 2010 during the 111th Congress by Congressman Peter King (R-NY) was ***H.R.5081; Broadband for First Responders Act of 2010***, which focused primarily on allocation of the D block to public safety. HR5081 garnered 81 co-sponsors in less than eight months, roughly evenly divided among House Republicans and Democrats. Additionally, Senators Lieberman (I-CT) and McCain (R-AZ) introduced legislation, ***S. 3625; First Responders Protection Act of 2010***, which provided D block allocation, $11 billion in funding derived from other spectrum auction revenues for build-out of the Public Safety Broadband Network, and an expanded representation on the current PSBL. The final piece of legislation introduced in the last Congress was offered by Senate Commerce, Science and Transportation Committee Chairman John "Jay" Rockefeller, IV, as ***S.3756; Public Safety Spectrum and Wireless Innovation Act of 2010***, which allocated D block to public safety and provided $11 billion in funding derived from "incentive" and other auction revenues.

Chairman Rockefeller reintroduced his legislation in January 2011 as ***S.28; Public Safety Spectrum and Wireless Innovation Act of 2011*** and declared public safety spectrum and the PSBN as his committee's highest priority in the new 112th Congress. In June 2011, the Senate Commerce Committee favorably reported out a bipartisan bill developed by Chairman Rockefeller and Ranking Member Kay Bailey Hutchison, ***S.911; Public Safety Spectrum and Wireless Innovation Act of 2011***, by a vote of 21-4. S.911 allocates D block to public safety, provides $11.75 billion in funding for the PSBN derived from "incentive" and other spectrum auctions, and creates the Public safety Broadband Corporation as an independent non-profit governance entity, as the new PSBL, to oversee the management and implementation of the PSBN. The bill is also designed to provide $10 billion from the aforementioned spectrum auctions to battle deficit reduction. The Congressional Budget Office's (CBO) July report estimated that the bill's auctions would derive $24.5 billion in revenue providing only $6.5 billion in deficit reduction, or $3.5 billion less than the bill sponsors had estimated. Chairman Lieberman and McCain reintroduced their own bill, ***S.1040; Broadband for First Responders Act of 2011***, in May, 2011, which again allocates D block to public safety, provides $11 billion in funding derived from other spectrum auctions revenue, and expands representation within the current PSBL.

Meanwhile, House Homeland Security Chairman Peter King introduced new legislation, ***H.R.607; Broadband for First Responders Act of 2011***, along with Ranking Member Bennie Thompson (D-MS), which allocates D block to public safety and provides $11 billion in funding derived from other spectrum auction revenue. HR607 currently has garnered 46 bipartisan co-sponsors, and awaits action by the House Energy and Commerce Committee, which is the committee with jurisdiction of spectrum policy in the House.

After holding four hearings since April 2011 on spectrum policy and the public safety broadband network, the House Energy and Commerce Committee recently circulated competing Majority and Democratic Staff Discussion Drafts that disagree on whether to auction or allocate D block, on how much funding to provide, where the revenue is acquired, and how the PBSN should be governed. The Democratic Discussion Draft is very similar to S.911, which is overwhelmingly supported by public safety as well as state and local governments. We have asked that the House Energy and Commerce Committee take up and vote on legislation immediately in an effort to move it through the legislative process.

Shortly before the August break, Senate Majority Leader Harry Reid (D-NV) proposed an amendment to the Budget Deal that included language largely taken from S.911, which would have allocated D block to public safety, provided $7 billion for build out of the PSBN as derived from "incentive" and other auctions, while establishing the PSBC and providing $13 billion for deficit reduction. The final agreement did not include the Reid Amendment, but the issue of spectrum policy and the public safety broadband spectrum needs is reportedly under consideration as part of the Joint Select Committee on Deficit Reduction, dubbed the Debt "Super Committee." The Super Committee held its first official meeting on September 8th.

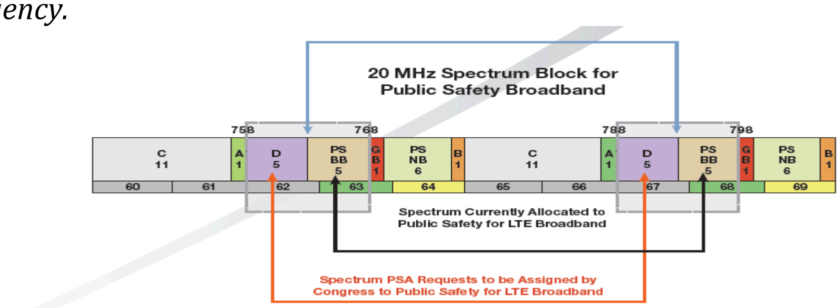
As a solemn reminder to the tragic events of September 11th, a 9/11 Report Card was issued by the Bipartisan Policy Center, and the National Security Preparedness Group Co-Chairs, former Governor Thomas Kean (R-NJ) and former Congressman Lee Hamilton (D-NY), who also chaired the 9/11 Commission. The men urged Congress, once again, to "immediately" allocate the D block spectrum to public safety to finally realize one of the last unmet recommendations of the 9/11 Commission to build a nationwide, interoperable, and mission-critical public safety broadband network before another strike or major disaster happens.

II. WHY THE D BLOCK

Excerpt: Public Safety Alliance, "America's First Responders Need Your Help!" July 2011

Public safety is currently the license holder of 10 MHz of broadband-ready spectrum in the 700 MHz band. As the only remaining portion of unlicensed 700 MHz spectrum on a nationwide basis, public safety must be allocated the D Block, which is directly adjacent to the public safety spectrum, in order to build out a 20 MHz broadband network. From a fiscal standpoint, allocating the D Block to public safety would be the most financially and nationally responsible use of the spectrum, as the build-out of a 20 MHz network split between two separate bands would cost taxpayers billions more than simply building one 20 MHz network on a single spectral band. Allocating the D Block to public safety will allow for a nationwide interoperable broadband network on a contiguous 20 MHz spectrum swath.

The D Block is the only spectrum capable of accommodating public safety's needs, due to the unique propagation characteristics of 700 MHz spectrum. The combined 20 MHz of spectrum would provide the framework for an ideal broadband network for first responders because it would provide enough capacity necessary to transmit mission critical real-time high resolution video, voice and data with the in-building penetration required by police, EMS and fire services when responding to emergencies. The robust network would be strong and efficient enough to provide mission critical-grade communication in the case of a natural disaster, terrorist attack or other emergency.



III. WHY BROADBAND

TODAY'S APPLICATIONS

Excerpt: Dr. Alan R. Shark, D. (2010). 700 MHz "D" Block Public Safety Application Needs Assessment. White Paper, Public Technology Institute.

How the 700 MHz D Block is ultimately allocated to public safety is critical to the deployment of a new and dynamic plethora of advanced high-tech public-safety applications. The 700 MHz band is exceptionally well suited for the new and demanding requirements of a new generation of video/data/voice devices.

The evolution of wireless communications continues at a rapid pace. In mid-2007 the iPhone was first launched - and lost in all the fanfare was that this phone was produced by a computer manufacturer and not a cell phone manufacturer. This device would change everything for consumers as every other manufacturer attempted to match or beat the iPhone. Today there are over 100,000 applications available, and there is no question that these devices have quietly morphed into powerful handheld computers that just happen to offer a decent phone as an "app."

The following applications are either being deployed piecemeal or are being planned for the near future. Because public safety agencies lack a common spectrum for the newer technologies, the cost of equipment is far greater than it would be if the applications highlighted below were located in a single 20 MHz spectrum block, with appropriate rules and standards.

- *Most local enforcement agencies have **mobile crime units** of some kind; some in the form of buses, or vans. For mobile command applications to take better advantage of the latest technologies and communications systems, they will require greater bandwidth and spectrum to better integrate high-speed, high-definition video, data, and voice communications. Typically, the equipment used includes mobile, fingerprint reading and analysis, video crime scene analysis, and blood sample analysis, as well as perimeter protection and monitoring, and scene ID authentication.*
- *When natural disasters, major structural fires, hazmat incidents, hostage situations, or terrorism incidents strike, a **mobile command center** is required to coordinate and establish a mobile command system. The command center serves as the central hub for receiving and analyzing various voice communication paths, data monitoring and analysis, bio-monitoring, 3D building schematics and diagrams, GIS mapping, individual first-responder tracking, vehicle assets placement and tracking (AVL), incident ID authentication.*
- ***Automated license plate reader** technology allows public safety officers to passively or actively scan vehicle license plates, either moving or parked. Data is retrieved from a specialized video camera and automatically sent to a*

database for immediate response. Such devices are particularly helpful with event management, "amber" or "silver" alerts, and seeking out individuals of interest.

- ***Mobile ticket writer*** *systems allow for near-instant license look-up with full driver picture display, along with address, driving record, and any outstanding warrants. This type of system has been proven to dramatically increase productivity in ticket writing and leads to greater law enforcement personnel protection. Moreover, mobile ticket writing systems help ensure officer safety, as he or she would know instantaneously whether the subject is more than merely a traffic violator.*
- ***Streaming video*** *from mobile devices require a huge amount of bandwidth – especially if offered as high-definition broadcast. Streaming video is required for mobile incident feeds and supplies critical visual information to various agencies and sites for improved coordination and multi-agency engagement.*
- *Leading city, county, and state agencies are increasingly relying on accessing* ***geospatial information*** *databases where building schematics, wiring, ventilation systems, street conduits, underground structures, pipelines, subways, and other critical infrastructures are displayed. Mashed-up data is considered essential in being able to quickly respond to incidents and crises requiring immediate analysis and response.*
- ***Mobile Video surveillance*** *offers public safety officials the ability to connect responding units within minutes and receive immediate feeds. The latest mobile video technology provides for extreme lowlight capture plus high-definition resolution. These must-have units also come with a large requirement for intensive bandwidth.*
- *Cities and counties are looking to purchase* ***multi-mode biometrics monitoring devices*** *that are either fixed or mobile. Fixed units are designed to be deployed in or around major transportation hubs as well as in high-risk government buildings and structures, and landmarks. Mobile units are designed to be deployed at planned incidents such as parades, festivals, etc, and to warn of potential threat. Mobile units may also be deployed when an incident may be about to occur or has already occurred, and precise measurements are needed to ascertain site safety for first responders and the general public.*
- *New technology provides* ***fire electronic command boards*** *at the site where they are most needed and shared simultaneously with other command centers. A mobile command center is required to coordinate and establish a mobile command system when natural disasters, major structural fires, hazmat incidents, or terrorism incidents strike. The command board serves as the central hub for receiving and analyzing various voice communication paths, data monitoring and analysis, bio-monitoring, 3D building schematics and diagrams, GIS mapping, individual first-responder tracking, vehicle assets placement and tracking (AVL), and incident ID authentication.*
- *Cities and counties have turned to* ***Automatic Vehicle Location (AVL) and telemetry systems*** *to better coordinate their dispatch of first responder units through improved tracking and system status management. ALS units can also*

broadcast key vital signs to medical experts in other locations, helping to better ensure life-saving care. With patient telemetry hospitals can be better prepared to offer life-saving measures before the patient arrives.

- *With a growing population it is more important than ever before to deploy technologies that can utilize **facial recognition** to seek out persons of interest, or to simply permit passage of authorized first responders to an incident or crime scene. Video analytics scans for visual anomalies, thus helping to track, guard, and monitor buildings, sites and events for suspicious behavior.*
- *Ideally, the benefits are obvious if every public safety vehicle has the capacity to view **floor plans and have access to records, photos, and other 3D graphical displays**. Each vehicle would be required to have a more powerful data terminal and screen capable of viewing high-definition video and audio. The irony here is that many believe the general public will have access to similar features with the next generation of broadband devices - slowed only by network capability and non-public-safety-grade equipment devices.*
- ***Telemedicine** allows emergency and trauma physicians to triage cases remotely, even while patients are in transit. The ability to transmit video and images of the patient in transit can save big dollars considering that each Level 1 trauma activation involves 18 to 20 people and costs the hospital $5,000. If a single physician or nurse triages the case by video, the system can prevent unnecessary trauma calls. (Hospitals and Health Networks (H&HN), 2009)*
- *Bomb disposal units are increasingly relying on **robots** to take over the dangerous task of finding and defusing bombs. But robots are also taking on other hazardous duties, and their capabilities are evolving rapidly.*
- *In recent years, the emphasis on measures to combat terrorism has led to the development of technologies to **detect nuclear, chemical and biological threats**. Sensor capable of identifying nuclear, chemical and biological threats and alerting authorities can potentially reduce the risk from future terrorist actions.*

FUTURE MISSION CRITICAL VOICE COMMUNICATIONS

Excerpt: Seybold, A. M. (2011, June 19). *LTE Support for Mission Critical Voice for Public*

Mission critical voice communication reflects the harsh realities on the emergency management scene: when every other commercial system is down, you expect mission critical voice to be there. The exacting standards for mission critical networks and devices disqualify many nascent technologies and devices in favor of proven, reliable standards. In a mission critical environment, all aspects of a device or technology must achieve interoperability, reliability, coverage, capacity, control and instant, real-time communications.

If LTE broadband can meet both the voice and the data requirements of the first responder community, a single device could be deployed that would provide not only *data/video interoperability, but voice interoperability as well. This would be an ideal situation and one that is worth pursing. However, existing narrowband spectrum should not be reallocated for other uses until such time as LTE broadband can and does meet all of the requirements for Public Safety mission critical voice as well as data and video services.*

LTE or fourth-generation (4G) wireless broadband was designed and implemented primarily as a data over broadband technology. Voice in the form of Voice over IP, which is being designed to implement voice calls in the traditional cellular fashion of dialing a number and completing the call using the LTE network as transport, is being developed. The issue is whether LTE can and will support other types of voice services, specifically Push-To-Talk (PTT) voice and most importantly, PTT off-network [point-to-point], when units are out of coverage of the network or when they need short-range communications in buildings and in other areas where the network does not provide coverage.

The standards for LTE are largely controlled by the 3GPP, an organization made up of hundreds of commercial members including chipset companies, infrastructure vendors, network operators, handset companies, software developers, and others. In order to add mission critical voice requirements to the LTE standard, the Public Safety community must petition the 3GPP for its inclusion AND there must be a number of other members of 3GPP that concur. Once (if) this happens, the amendment to the standard is assigned to a future release of LTE and when that release is being worked on, the amendment will be considered.

In order for the amendment to the standard to be considered, all of the requirements must be defined and support must be garnered from members of the 3GPP. At present, there is no incentive for network operators that largely drive the direction of 3GPP, to embrace mission critical voice, especially the part of mission critical voice that is of paramount importance to Public Safety: The ability to communicate between devices without having to make use of a network. Commercial network operators are not inclined to agree to this type of voice communications because they won't have control of their customers and the minutes of use cannot be billed to the customer.

Therefore, Public Safety will have a difficult time convincing the 3GPP to address the issue of mission critical voice. If a non-standard workaround can be and is developed, it would mean that the devices used by Public Safety would not be nearly as standard as the devices being envisioned today for data and video, thus the cost of these devices would be considerably higher.

However, voice over LTE will happen. It might take longer than many people believe, and it will certainly be implemented in stages. The first voice over LTE smartphones will be available on commercial networks by the end of this year, and the first PTT LTE devices will be tested. Initially, neither of these voice services will meet all of the voice requirements of the Public Safety community. The first PTT service will probably be PTT over LTE for non-mission critical voice communications that will be bridged to *existing narrowband P25 voice systems in order to provide for interoperability between narrowband voice and LTE PTT services.*

For those trying to plan upgrades to or expansion of their existing narrowband voice networks, it is possible that voice over LTE, both on and off-network, will eventually be developed to provide all of the voice requirements for mission critical on and off-network services. ***If there is funding for research and development available from the federal government,*** *the time frame will most likely be shortened. In either case, it will take time to first build out the nationwide broadband network, then it will take time for Public Safety to learn how to incorporate data and video into their everyday incidents and then how to integrate voice over LTE into their systems over time.*

Excerpt: National Public Safety Telecommunications Council Broadband Working Group. (2011). Mission Critical Voice Communications Requirements for Public Safety. White Paper.

LTE will be able to provide some of the voice capabilities needed by the Public Safety community. The questions remaining are how long will it take to implement the rest of these requirements, how much will it cost, and whether it is better in the near future to integrate voice and data services in the back-end network but not necessarily over the airlink. There is a lot of work to be done to transition from traditional narrowband voice to voice over LTE, and at this point no one knows how long it will take or even if all of Public Safety's requirements can be fully met on a broadband network.

The key elements for the definition of Mission Critical voice include the following:

- ***Direct or Talk Around:*** *This mode of communications provides public safety with the ability to communicate unit-to-unit when out of range of a wireless network OR when working in a confined area where direct unit-to-unit communications is required.*
- ***Push-to-Talk (PTT):*** *This is the standard form of public safety voice communications today - the speaker pushes a button on the radio and transmits the voice message to other units. When they are done speaking they release the Push-to-Talk switch and return to the listen mode of operation.*
- ***Full Duplex Voice Systems:*** *This part of the definition describes the use of Public Safety devices. This form of voice communications mimics that in use today on cellular or commercial wireless networks where the networks are interconnected to the Public Switched Telephone Network (PSTN)*
- ***Group Call:*** *This method of voice communications provides communications from one-to-many members of a group and is of vital importance to the Public Safety community*
- ***Talker Identification:*** *This provides the ability for a user to identify who is speaking at any given time and could be equated to caller ID available on most commercial cellular systems today.*

- ***Emergency Alerting:*** *This indicates that a user has encountered a life threatening condition and requires access to the system immediately and is, therefore, given the highest level or priority.*
- ***Audio Quality:*** *A vital ingredient to Mission Critical Voice. The listener MUST be able to understand without repetition, and can identify the speaker, can detect stress in a speaker's voice, and be able to hear background sounds as well without interfering with the prime voice communications.*

Each of these components, which make up the requirements for Mission Critical Voice, are essential. In order to be able to provide Mission Critical Voice over any type of network the definition for each of these elements must be fully understood. It is, however, important to understand that for a network to fully support Public Safety Mission Critical Voice Communications each and every one of these elements must address part of the overall voice communications services supported by the network.

SPECTRUM & CAPACITY

Excerpt: Rysavy, Peter. "Public Safety Spectrum." July 2011.

The amount of capacity in wireless networks depends on a variety of factors, but in general, mobile-broadband networks have significantly lower capacity than fixed-broadband networks. Capacity can be calculated by assessing the spectral efficiency of different wireless technologies, a value that is represented in bits per second per Hertz of spectrum (bps/Hz). While new technologies such as LTE are spectrally more efficient than prior technologies, all wireless technologies are reaching what is called the Shannon bound, a law that dictates the maximum spectral efficiency that a technology can achieve relative to noise. By knowing the radio channel size and the spectral efficiency of the wireless technology, one can estimate the aggregate capacity of a cell site. LTE in its initial deployments has a spectral efficiency value for the downlink of about 1.5 bps/Hz per sector. For the uplink, it is .65 bps/Hz.

Given the application requirements discussed in the next section, these capacity values, even for 20 MHz are quite finite. The capacity in 10 MHz, as is made clear below, is simply too limiting to provide a broadband network that can accommodate the needs of first responders.

There are multiple factors that are fueling growth in data usage including:

- ***Faster networks.*** *The faster that data can be exchanged, the more likely it is that applications will take advantage of the speeds, especially since faster speeds can mean less waiting time for workers.*
- ***More network‐enabled devices.*** *New device categories such as tablets and netbooks are expanding overall data consumption, especially because of the delivery of highquality video. Just as consumers and enterprises are adopting these new device categories, so will first responders.*

- ***Increasing computing speeds.*** *The faster the platform can compute, the more data an application can process in real time.*
- ***Higher screen resolution.*** *Greater screen resolution corresponds to higher resolution video options for users.*
- ***Embedded modems.*** *An increasing number of laptops and tablets come with embedded 4G modems, facilitating the use of mobile broadband service.*

The question is how much bandwidth do applications actually need.

- ***Voice over IP -*** *10 thousand bits per second (kbps) to 20 kbps (both downlink and uplink directions.)*
- ***General-purpose audio to record all sounds*** *- About 100 kbps.*
- ***Video -*** *Ranges from 200 kbps on a small-screen device like a phone, to 1 million bits per second (Mbps) for medium resolution on a laptop, to 5 Mbps for high definition.*
- ***Web browsing*** *- Usually requires about 1 Mbps or higher to provide good response time.*

By comparing these throughput requirements against the capacities listed in the previous section, one can see that just a handful of first responders could easily consume the capacity of a 10 MHz LTE network. LTE in 10 MHz has a downlink capacity of 7.5 Mbps. Thus, 8 downlink streams at 1 Mbps each would consume the capacity of the cell sector. On the uplink capacity is even more constrained at 3.25 Mbps where just 4 uplink streams would consume capacity. For example, these streams could be video from patrol cars at a crime scene.

Public-safety applications will increasingly demand higher bandwidth. The same innovation shown in commercial broadband will extend to public-safety broadband. In the February 2011 report "Cisco Visual Networking Index: Global Mobile Data Traffic Forecast Update, 2010-2015," Cisco predicts a 92% compound annual growth rate in mobile traffic. There is no reason that such trends do not also apply to Public Safety. Examples of public-safety applications include:

- *Wireless video surveillance.*
- *Aerial video from a helicopter over a scene fed to personnel below.*
- *Video-based training to remote emergency workers.*
- *Real-time license plate recognition.*
- *Testimony based on video transmitted from an emergency-services vehicle or command post.*
- *Sending and receiving high-resolution pictures.*
- *In-field biometrics (such as iris and fingerprint identification).*
- *Automated vehicle location and navigation.*
- *Medical applications such as telemedicine, patient records, and high-resolution video to enable medical services performed at a scene of an accident.*

It is important to note that another aspect of some public-safety applications is that they demand bandwidth continuously. For example, a patrol car in an emergency situation may need to transmit a constant video stream.

PRIORITY vs. PREEMPTION

Excerpt: Rysavy, Peter. "Public Safety Spectrum." July 2011.

There are arguments for alternative approaches to dedicating spectrum for Public Safety, such as sharing commercially-allocated spectrum between first responders and commercial operators, with the commercial operator serving as the primary user or licensee. This is a bad idea for a multitude of reasons.

The first reason is that the needs of commercial customers and Public Safety are inherently different. Commercial networks are developed in a highly competitive environment where operators invest in a way to provide services at the lowest possible cost to customers. These low costs are a major factor in what is driving the broadband market. First responders, however, need hardened networks that are extremely reliable. This hardening includes items such as long term backup power, redundant backhaul, diversified routing, and explosion proof sheltering, thus significantly increasing the cost of the network, and likely not making it viable from a competitive aspect for the private sector.

Sharing of spectrum also assumes that public-safety applications will obtain the bandwidth they need when they need it from the commercial entity. This assumption, however, is fraught with risk for the following reasons:

- *Policies implemented by commercial operators may not sufficiently address public safety needs. Policies, such as reserving certain amounts of bandwidth for commercial customers, may result in insufficient capacity for public-safety applications in emergency situations.*
- *Prioritization schemes may not work correctly. In an emergency situation where there is massive demand on the network from both constituencies, it is possible that prioritization schemes will not work as planned simply because they may never have been tested under such extreme conditions.*
- *Users may defeat prioritization schemes. It is already common for users to hack their devices, especially smart phones, to access services not in their current service plans. These modifications could defeat the prioritization schemes at exactly the time they are most needed.*

Nevertheless, if Public Safety has control of the spectrum and they wish to lease part of their network capacity to other entities, this can be feasible and even desirable for defraying costs, so long as Public Safety can specify the terms of such arrangements, can implement the appropriate preemption capabilities, and so long as the underlying network is built to address the specific requirements of Public Safety.

Excerpt: Seybold, A. M. (2011, September 1). Cell Phones and Nature. Retrieved September 13, 2011, from AndeySeybold: http://andrewseybold.com/2617-cell-phones-and-nature

The East Coast has suffered a double whammy as we all know. First was the 5.8 earthquake followed by Hurricane Irene, which was not as bad as was feared but still bad enough that the damage will take a long time to repair. Both of these events caused problems for the commercial wireless networks but in very different ways, pointing out the major differences between network overload and cell site failures.

In both of these cases there were network issues. During the earthquake the problem was simple: The networks stayed up but they were overloaded and could not process all of the requests for service. This is the same scenario that has been experienced with landline phones for years. Remember how difficult it used to be to get a dial tone on Mother's Day? Perhaps you remember when after an earthquake in California or during the wildland fires you could not get a call through to your relatives using the wired network?

While the cause of wired and wireless phone system overloads are different, the results are the same. The network is up and running but the number of people trying to make calls simply overwhelms the network. In the case of wired phones, the reason is that after your dedicated line reaches the nearest central office your call is joined with all of the other calls on a cable or microwave link. This link transfers the requests and the calls overloaded the link since all of these systems are built on the premise that not all phone users will want to make a phone call at exactly the same time. Therefore, the wired phone systems were designed to handle a normal, expected traffic load with extra capacity for peak call periods, but they were not designed for times when demand is unusually high. The lines and switches were jammed and people could not get dial tone and had to wait until the demand subsided.

For the sake of simplicity, let's assume that within each sector the maximum number of voice calls that can be handled is 100. A sector's normal traffic load might be thirty calls at the same time, peaking at sixty calls in a single cell sector during busy periods. Good cellular design dictates that reserve capacity be built into each cell sector so that others entering that sector from another have capacity on the new sector and are not disconnected as they move from sector to sector.

The sector becomes overloaded when demand for service exceeds the maximum number of calls that can be processed in that sector, in this case 100, so if there are 120 people within the sector some will not have network access. The way you gain access to the network is that your device (or the network in the case of an incoming call) sends a request on what is typically called the signally channel. This channel is not only used to request a call but also for the network to track the location of the device so it can be found during an inbound call as well as to facilitate the hand-off to *the next sector when the phone is moving. In some networks this signaling channel is also used for SMS traffic, which uses some of the capacity of the signaling channel.*

If there are too many devices trying to access the network within a cell sector, the signaling channel becomes overloaded and some customers' requests will not even reach the network (this is one reason priority access for public safety is not a viable option). So there are two issues, the total number of calls a sector is capable of handling, and the amount of traffic on the signaling channel. Even if more spectrum is allocated to a cell sector, while the number of calls that can be handled by that sector increases, there is still a finite number the sector is capable of processing and completing.

On the data side, even fewer data sessions per sector are normally supported. In normal usage, data bursts to and from the device will permit more customers to make use of the broadband data side of the system. However, if a number of customers are streaming video up or down, the total number of broadband data users is diminished greatly. Even in normal times we have seen the results of cell site sector overloading. AT&T had this type of problem as the iPhone took off a few years ago and many of its customers started using a lot of data services. It is possible that one sector or multiple cell sites are completely overloaded due to demand but calls can still be made and received a few miles away where the demand is less.

What happened during the earthquake was that everyone reached for their phones at once. The networks worked perfectly during the aftermath of the quake but they were simply overloaded on both the voice and the data side. Calls could not be made or received, calls were dropped, video taken of damage could not be sent, and SMS messages did not get through. No matter how much spectrum we have or how robust the commercial operators build these networks, we will have network overloading during major events.

This is not a new problem. You might recall that during the Oklahoma bombing the radio and TV stations were telling people within the affected areas not to use their phones so the commercial systems could be used to augment the public safety channels. During the earthquake, I am not aware of a single cell site failure so the bottom line is that in this instance, the problems experienced were network overloading and this will never be solved no matter how much spectrum we throw at it and no matter how many more cell sites are built. It is not possible for anyone to build a commercial wired or wireless network that will not reach saturation at some point, due to some type of major incident. The same is true, by the way, with the Internet for all of you who plan to rely on it and store all of your data in the cloud.

One advantage to the commercial wireless networks is that the network operators can do some on-the-fly network management. Especially the newer 3G and 4G networks have tools built in that enable pro-active traffic management by changing antenna patterns to shrink the radius of a cell site, to overlap cell sectors in a given area, and to try to balance the load. However, even with all of this new technology there comes a *point where a cell sector, and possibly many cell sectors, will be overloaded and this will happen over and over again. It is more severe during an event such as an earthquake because once the event is over, everyone reaches for their phones at once. During a longer incident, say a hurricane, the traffic does not usually peak as quickly and therefore the networks are generally able to handle the additional traffic.*

Two different acts of nature caused incidents resulting in two different types of commercial network issues. During the earthquake, the networks stayed up but were overcrowded, a situation that will be repeated regardless of what we do, and the hurricane saw more spot outages due to power and communications links problems. In both cases these types of problems cannot be fixed by an FCC inquiry or a change in the rules, they will continue to happen. There is no such thing as a network that can withstand overcrowding or wind and flooding.

MIGRATION OF LMR TO BROADBAND

Summary: Sen Hutchison, K. B., & Sen Rockefeller, J. D. (2011). S. 911: The Public Safety Spectrum and Wireless Innovation Act of 2011. United States Senate, U.S. Senate Committee on Commerce, Science, and Transportation.

S. 911 requires the Commission to conduct a study and submit a report to the appropriate committees of Congress and to the Corporation on the spectrum used by public safety licensees or for public safety services pursuant to section 337(f) of the Communications Act of 1934 (47 U.S.C. 337). The report shall inventory the spectrum assigned to public safety use; and include the amount of spectrum allocated to public safety use; the number of licensees and amount of spectrum assigned to each licensee; a general description of technologies and systems in each band; an approximation of network coverage, as appropriate, of major systems (such as an estimation of land mobile radio coverage by population) in major metropolitan areas; and an approximate number of users of major systems, such as the number of first responders using land mobile radio, in major metro areas; assess if spectrum is adequate to meet the current and future needs for public safety services; and assess the opportunity for return of any additional spectrum to the Commission for reallocation.

IV. HOW MUCH WILL IT COST

Excerpt: Public Safety Alliance, "America's First Responders Need Your Help!" July 2011

The Federal Communications Commission's (FCC) National Broadband Plan states that the build-out of a 10-MHz broadband network will cost between $12 and $16 billion over the next ten years. The cost of building a 20-MHz network is the same as building a 10 MHz system, and could actually cost less. The FCC's plan requires the federal government to pay for the build-out.

However, if public safety were able to leverage the excess network capacity, and utilize existing public safety infrastructure when building out the network while securing partnerships with private industry partners, the actual cost to local, state, tribal and federal governments would be considerably less. A combination of leasing excess capacity, prioritized federal grant programs and revenue from other auctioned spectrum would help build and sustain the nationwide interoperable public safety broadband network, while creating a budget neutral funding model.

The recently released Congressional Budget Office (CBO) report on the estimated costs and revenues for S. 911 will provide more than $6.5 billion for deficit reduction. The CBO's estimated costs and revenues for S. 911 indicate that the FCC's auction of spectrum would generate $24.5 billion in auction revenues which would fully fund the $11.75 billion broadband network for first responders.

The CBO's analysis of S.911 reflects the sentiments of Senators Rockefeller, Hutchison, Schumer and others that this bill will help save lives, lower the national deficit and implement a final outstanding recommendation of the 9/11 Commission, without costing the American taxpayer.

Excerpt: Gramp, K., Willie, S., Pickford, M., Stocking, A., & Webre, P. (July 2011). COST ESTIMATE: S. 911 Public Safety Spectrum and Wireless Innovation Act. Congressional Budget Office.

S. 911: The Public Safety Spectrum and Wireless Innovation Act of 2011 would establish a new entity, the Public Safety Broadband Corporation, to build, operate, and maintain a broadband network for public safety agencies that would be available across the country on a specific spectrum band. The bill would grant a license to the corporation to use 22 MHz spectrum nationwide: the 10 MHz "D block" spectrum (discussed above) and 12 MHz that has been allocated for public safety purposes under current law. The license would have an initial term of 10 years and would be renewable for additional 10-year terms if the FCC determines that the corporation has met the requirements set out in S. 911.

The bill would appropriate $11.75 billion to the corporation from spectrum auction receipts to build a nationwide network of wireless broadband. The corporation also would be authorized to borrow funds from the public and incur other forms of indebtedness. It would be given temporary authority to borrow funds from the Treasury through the NTIA for amounts necessary to carry out its responsibilities; this borrowing authority would terminate once certain auctions have begun. CBO expects that the corporation would borrow amounts sufficient to allow the network to be developed and operated, independent of the timing of the auctions under the bill.

S. 911 also would authorize the corporation to assess and collect several different fees in amounts sufficient to cover, but not exceed, its annual operating expenses. Specifically, the corporation would be authorized to assess:

- *A subscription fee from each entity using the public safety network;*
- *Fees from commercial services that choose to lease the network's capacity on a secondary basis; and*
- *Fees from entities that access equipment or infrastructure built and maintained by the corporation.*

CBO estimates that establishing the corporation would increase direct spending by $12.5 billion over the 2012-2021 period. This amount includes amounts appropriated to the corporation by S. 911 for capital expenditures and net operating losses that CBO anticipates would be generated in the first few years of the corporation's operations.

CAPITAL EXPENDITURES TO BUILD OUT THE NETWORK

CBO estimates that the corporation would spend $11.5 billion over the 2012-2021 period to build a nationwide wireless broadband network.

Based on information from the FCC and industry experts, CBO estimates that the corporation would develop a network of about 45,000 sites to serve 95 percent of the Cost of Build Out population by 2018 at an average cost of about $170,000 per site. That estimate is higher than the costs typically incurred by private firms because of the added reliability and security needed for public safety systems and the cost of independent capabilities specified in the bill. CBO estimates that meeting the goal of nationwide coverage would require several thousand additional sites to be built in rural areas at roughly double that unit cost. Because S. 911 would provide funding for the additional sites, CBO estimates that most of those sites would be operational by 2021.

NET OPERATING INCOME

The corporation's annual cash flows from operations would depend on how quickly the network is built and used. Operating costs would be largely tied to the number of sites that are built and on the administrative costs of serving public safety users. CBO based its estimate of operating costs on historical trends for wireless firms as well as FCC and industry projections of the costs associated with sites that have been built or are leased from other companies. Income from customers would depend on the network's available capacity and market conditions. For this estimate, CBO assumes that the corporation would be able to sell virtually all of its available capacity by 2021 at prices that are consistent with industry trends for retail and wholesale transactions.

Based on that information, CBO estimates that the corporation's operating costs would exceed its income by about $1 billion over the 2012-2021 period. Operating losses are typical for new entrants in the wireless market because of the lag between start-up costs and income from retail and wholesale customers. CBO estimates that the corporation would experience annual losses ranging from about $200 million to $400 million a year in the first few years of operation but would start to generate sufficient income to offset those losses by the end of the 10-year period. CBO also expects that the *corporation's losses would be higher than for commercial firms because the towers located in areas with very low population densities may not generate enough income during this period to cover the added operating costs.*

STATE AND LOCAL GRANTS

S. 911 would appropriate $250 million from spectrum auction receipts for matching grants to assist state, local, and tribal governments in developing effective ways to use the public safety network created by the corporation. To implement the program, the Department of Commerce would be allowed to borrow that amount from the Treasury beginning on October 1, 2011. Once auction proceeds become available, they would be deposited into a State and Local Implementation Fund and would be credited as an offset to borrowed funds and cover other program expenses, subject to the $250 million limit.

RESEARCH AND DEVELOPMENT PROGRAMS

S. 911 would appropriate up to $1.5 billion from auction receipts for two research and development (R&D) programs related to communications technologies. Funding would be provided for each of the fiscal years 2012 through 2016 in the following amounts: $100 million a year would be allocated for a new research program coordinated by the National Institute of Standards and Technology (NIST) on systems for public safety users and $200 million a year for additional research conducted by NIST, the National Science Foundation, and the Defense Advanced Research Programs Agency.

Because of the time needed to conduct auctions and issue licenses to the winning bidders, CBO estimates that there would not be any funding available for the R&D programs until fiscal year 2014. As a result, we estimate that the funding available for those initiatives would total $900 million over 2012-2021period.

TRANSFER OF THE D BLOCK SPECTRUM

Current law directs the FCC to auction commercial licenses for 10 MHz of spectrum known as the "D block" and to deposit the proceeds in the Treasury. (The D block covers spectrum between the frequencies from 758 MHz to 763 MHz and between 788 MHz to 793 MHz.) Under current law, CBO estimates that such an auction will be held by the end of 2012 and will generate receipts of $2.75 billion over the 2012-2013 period.

S. 911 would reallocate the D block from commercial to public safety uses, at no cost to those entities. CBO estimates that forgoing the offsetting receipts from the auction of the D block would increase direct spending by $2.75 billion.

V. HOW WILL IT BE FUNDED

Excerpt: Gramp, K., Willie, S., Pickford, M., Stocking, A., & Webre, P. (July 2011). COST ESTIMATE: S. 911 Public Safety Spectrum and Wireless Innovation Act. Congressional Budget Office.

S. 911 would amend existing law regarding the FCC's authority to auction licenses to use the electromagnetic spectrum. It would extend the commission's auction authority, which is currently scheduled to expire at the end of fiscal year 2012, through 2021. The FCC would be directed to auction certain frequencies by January 31, 2014, including 95 megahertz (MHz) of spectrum that is currently used by the Department of Defense (DoD) and other agencies. Other provisions would establish a statutory framework for what are known as "incentive auctions," in which private firms (primarily television station owners) would voluntarily relinquish some or all of their existing spectrum rights in exchange for a payment from the FCC. That spectrum would then be available for new licensed or unlicensed services. To implement incentive auctions, the bill would:

- *Authorize the FCC to spend auction receipts to pay firms that voluntarily relinquish their licenses;*
- *Appropriate up to $1 billion from auction receipts to create an Incentive Relocation Fund administered by the National Technology Information Administration (NTIA). The fund would be used to pay television broadcasters who do not relinquish their licenses for costs the FCC would impose to change their channel assignment as part of the process of clearing spectrum for nonbroadcast services. The fund also would cover certain expenses incurred by cable operators and other distributors of television programming.*
- *Allow the FCC to spend auction receipts to compensate television broadcasters who do not relinquish their license for any modifications made by the FCC to the quality or scope of their coverage as a result of efforts to clear spectrum for nonbroadcast services; and*
- *Allow the FCC to make some television broadcast frequencies available for unlicensed use if the amount of spectrum awarded through competitive auctions is at least 84 MHz.*

CBO estimates that enacting those provisions would reduce direct spending by $24.5 billion over the 2012-2021 period. That estimate reflects the expected value of offsetting receipts (based on the outcomes of various scenarios regarding the quantity and quality of frequencies likely to be auctioned over this period), net of direct spending to compensate existing licensees affected by the auctions.

Establishes in the US Treasury the "State and Local Implementation Fund". The Treasury is authorized to deposit into or credited to the State and Local Implementation Fund (1) any amounts specified in section 401; and (2) any amounts borrowed by the Assistant Secretary. The Assistant Secretary is authorized to borrow from the general fund of the Treasury beginning on October 1, 2011, such sums as may be necessary, but not to exceed $250,000,000, to implement section 222. The Assistant Secretary is required to reimburse the general fund of the Treasury, without interest, for any amounts borrowed as funds are deposited into the State and Local Implementation Fund.

Summary: Sen Hutchison, K. B., & Sen Rockefeller, J. D. (2011). S. 911: The Public Safety Spectrum and Wireless Innovation Act of 2011. United States Senate, U.S. Senate Committee on Commerce, Science, and Transportation.

S. 911 establishes the "State and Local Implementation Gran Program" that is to be administered by the Assistant Secretary in consultation with the Corporation. The purpose of the grant program is to make grants to States to assist State, regional, tribal, and local jurisdictions to identify, plan, and implement the most efficient and effective way for such jurisdictions to utilize and integrate the infrastructure, equipment, and other architecture associated with the nationwide public safety interoperable broadband network to satisfy the wireless communications and data services needs of that jurisdiction, including with regards to coverage, siting, and other needs. The matching requirement for the grants is 80% of eligible costs but the Assistant Secretary can waive, in whole or in part, the requirements for good cause shown if the Assistant Secretary determines that such a waiver is in the public interest.

Six months after the establishment of the bylaws of the Corporation the Assistant Secretary, in consultation with the Corporation, shall establish requirements relating to the grant program, including (1) defining eligible cost; (2) determining the scope of eligible activities for grant funding; and (3) prioritizing grants for activities that ensure coverage in rural as well as urban areas. In carrying out the grant program, the Assistant Secretary shall require each State to certify in its application for grant funds that the State has designated a single officer or governmental body to serve as the coordinator of implementation of the grant funds.

VI. HOW WILL IT BE MANAGED

Alcatel-Lucent. (2010). Long Term Evolution (LTE) for Public Safety: Enabling Flexible Business Models. White Paper.

STATE AND LOCAL DEPLOYMENT OPTIONS

The following three deployment options each have positive and negative factors. For all options, it is important to understand the requirements, resources and risks.

- *CAPEX model – All equipment and software is purchased, and ongoing support is provided through in-house personnel.*

- *Managed model – All equipment and software is purchased, but the ongoing support is either wholly provided by another party, or the support is shared by another party and in-house personnel.*
- *Hosted model – Network access is provided by another party and leased to a public safety entity for a monthly fee.*

***In the CAPEX model**, the overall network is owned and managed by one or more public safety entities. These entities take full responsibility for purchasing all network elements and software, and they employ in-house personnel to build, manage, operate and maintain the network. Individual agencies may be able to remotely monitor network health.*

Mission-critical networks are built with complete geographic redundancy to eliminate any single point of failure. This approach increases costs for core network equipment, beyond what is usually required for commercial networks. Initial upfront costs can be offset — and ongoing OPEX costs can be reduced — through government grants and incentives, along with any reallocated monthly per-subscriber fees (which may currently be paid to commercial broadband wireless service providers). The extent of upfront costs depends on: the scale of deployment (local or regional), whether the core network is shared among multiple areas or entities and how deployment is scheduled (gradually over years or within a shorter time period). With the CAPEX model, the public safety entity must also employ skilled personnel for network design, operations, maintenance, security and technical support, as well as program and project management. For a small deployment, these expenditures might not be economically viable.

The state and local public safety entity has full control over the network. A dedicated network in the 700 MHz band provides operational benefits, along with potential savings on margins imposed by service providers. With the proper know-how in place, a self-managed network can also offer an "a-la-carte" selection of applications and services customized to user needs in the target area, which could be local, county or another public sector. On the other hand, smaller networks would not benefit from the economies of scale a commercial operator might be able to realize. For example, commercial operators could gain efficiencies by leveraging their existing commercial resources to manage — and possibly build — the public safety network.

The CAPEX model can be a good option for local and state public safety entities that deploy their own network as long as they have "critical size." Critical size is determined by comparing the total allocated costs with the cost of an equivalent outsourced or managed service.

*The **managed model** is a hybrid, combining elements of the CAPEX and hosted models. With the managed model, the public safety entity is responsible for ensuring that network elements are appropriately owned and deployed. But it contracts with another party to manage and/or operate the network. Leased lines connect the* *network to the Operations, Administration and Maintenance (OA&M) center. Individual agencies may be able to remotely monitor the health of the network.*

Similar to the CAPEX model, this model requires each public safety entity to purchase all the equipment and software and contract for the required deployment services. Depending on the network architecture, these costs can vary significantly. Though in this model, cost savings are possible by contracting management functions with another party. For the highest Quality of Service (QoS), management services should go beyond traditional network monitoring and provide a performance management platform that proactively monitors for predetermined thresholds, along with preventive maintenance to ensure all network elements are running at peak efficiency. In doing so, the network is managed proactively to maintain network availability while ensuring a high degree of service uptime.

The managed model offers flexibility in terms of the management functions contracted. For example, a public safety entity could have another party provide end-to-end operational support, using a service-centric approach. This approach provides operational support from the core through the network to the end user. Contracting one party to provide full operational support eliminates finger pointing and the need to address multivendor management requirements.

The managed model provides a degree of control to each public safety entity. Network elements are deployed at a site chosen (and often owned) by the public safety entity. Owning the assets allows each public safety entity to decide when to upgrade the network and implement its own security platform. By contracting with another party to provide management services, the public safety entity will have a predictable monthly fee with lower IT and administrative headcount. It will also require less investment in network management tools and training.

The ***hosted model*** *allows each public safety entity to use network assets that are owned and managed by another party. These assets are usually shared among several similar types of customers with similar needs, creating economies of scale for both capital and operational expenses. While core infrastructure is shared, Radio Access Networks (RANs) are usually owned — and may be unique to — each individual public safety entity. The shared core provides the benefits of the platform while reducing startup costs and ongoing operations costs.*

With a hosted model, the public safety entity pays a consistent, predictable periodic fee for network access. The fee is usually a function of some known factor, such as the number of end users, devices or usage. This model also eliminates the need to plan and allocate funding for network upgrades, maintenance contracts and ongoing training for operations. These expenses are all handled by the hosting provider, who is responsible for keeping the platform current, resolving all technical issues and ensuring the appropriate level of service.

A hosted model architecture, where a non-public safety entity is the host — thereby owning a portion of the core and handling OA&M activities. The hosted core may include all functions related to mobility control, bearer management, gateway selection and authentication, messaging center, device management center, subscriber databases and Quality of Service control. The public safety portion of the core consists primarily of gateways to provide external connectivity and IP addressing. Both fractional cores could be physically separate. This approach accommodates large implementations and can eventually serve multiple jurisdictions. Transport is split between public safety-owned backhaul — for example, within a given jurisdiction — and a third-party transport cloud that carries traffic (mainly signaling) toward the hosted core. Individual agencies may be able to remotely monitor the health of the network.

FEDERALLY CHARTERED INDEPENDENT NON-PROFIT CORPORATION

Summary: Sen Hutchison, K. B., & Sen Rockefeller, J. D. (2011). S. 911: The Public Safety Spectrum and Wireless Innovation Act of 2011. United States Senate, U.S. Senate Committee on Commerce, Science, and Transportation.

S. 911 assigns the license 20 MHz of spectrum to the independent Public Safety Broadband Corporation (PSBC). Term of license is 10 years. The Corporation can renew the license for 10 more years if the Corporation demonstrates that it met the duties and obligations set forth in the Act.

The Corporation will be incorporated in DC and will be subject to DC's Non-Profit Corporation Act (sec. 29–301.01 et seq., D.C. Official Code). The PSBC needs to have headquartered out of DC. Members of the initial BoD will need to incorporate the PSBC in DC. The Board will consist of:

- *Non Federal Officials – Secretary of Commerce will appoint:*
  - *At least 3 individuals to represent the interest of the states, localities, tribes, and territories. The appointment needs to ensure geographic and regional representation and ensure rural and urban representation.*
  - *At least 3 individuals to represent the interests of public safety. The appointees must be individuals who have served or are currently serving as public safety professionals.*
- *5 Other BoD comprised of experts in commercial cellular services, communications and network managers, financial managers, corporate leaders, and or additional state, local and public safety officials.*
- *Four Federal Officials*
  - *The Secretary of Commerce.*
  - *The Secretary of Homeland Security.*
  - *The Attorney General of the United States.*
  - *The Director of the Office of Management and Budget.*

Each non-Federal candidate for the Board must be able to meet at least one of the following criteria:

- *Expertise in public safety;*
- *Technical expertise regarding broadband communications, including public safety;*
- *Network expertise in building, deploying and operating commercial networks; and*
- *Financial expertise in funding and financing telecommunications networks.*

The Secretary must appoint at least one individual satisfies each of the criteria listed above to serve on the Board of Directors.

Board members may not accept consulting or advisory or other compensatory fee from the Corporation. Board members may not be associated with the Corporation or any affiliated company. Non-Federal Board members also can not be officers or employees of the US Government or the District of Columbia and they must be a citizen of the United States to be a Board of Officer.

Term of Office - *Federal members of the Board will serve as members of the Board for the life of life of the Corporation. Non-Federal members shall serve for 3 years. No non-Federal Board may serve more than 2 consecutive 3-year terms. Board serves until successor has taken office or the end of the calendar year in which the Board's term has expired, which ever is earlier. Term of the initial non-Federal Board members will be:*

- *4 members serve for 3 years;*
- *4 members serve for 2 years; and*
- *3 members serve for 1 year.*

Vacancies will be filled in the same manner as the original member was appointed.

Appointment of the Chair *- The Secretary of Commerce will select the Chair of the Board from among the non-Federal Board. The Chair will serve for 2 years term. The Chair may not serve more than two consecutive terms.*

Removal of non-Federal Board Members *- The Secretary of Commerce can remove the Chair or any other non-Federal Board member for good cause. Non-Federal Board members may also be removed by a majority vote for conduct that is detrimental to the Corporation and a request from the Secretary of Commerce to remove the Chair Board to be determined by the Board to be detrimental to the Corporation.*

Meetings – *The meetings will scheduled in accordance with the bylaws of the Corporation but the Board is required to meet at least once a year and at the call of the Chairperson. The meetings of the Board, including any committee of the Board, shall be open to the public. The Board may, by majority vote, close any such meeting* *only for the time necessary to preserve the confidentiality of commercial or financial information that is privileged or confidential, to discuss personnel matters, or to discuss legal matters affecting the Corporation, including pending or potential litigation. Eight members of the Board shall constitute a quorum, including at least 6 non-Federal members of the Board. Attendance at the meetings can be in person, via telephone or videoconference.*

Compensation *– Members of the Board serve with without pay. Board members will be allowed to per diem allowance for travel expenses at rates authorized for an employee of an agency under subchapter I of chapter 57 of title 5, United States Code.*

Corporation Staff – *The Board shall appoint the CEO and other officers and employees. The Board will set the terms and rates of compensation for the CEO and other officers and employees. The CEO may appoint employees as necessary. All employees and officers serve at the pleasure of the Board. To serve as and officer of the Corporation, you must be a US citizen. No political test or qualification can be used in selecting, appointing, promoting or other personnel actions with respect to officers, agents or employees of the Corporation. The Federal Board members shall jointly approve the compensation, including benefit plans and salary ranges, for officers and employees of the Board. No officer or employee of the Corporation may receive any salary or other compensation from any sources other than the Corporation for services rendered during the period of employment. Service by any officer on boards of directors of other organizations, on committees of such boards, and in similar activities for such organizations shall be subject to annual advance approval by the Board. No officer or employee of the Board or of the Corporation shall be considered to be an officer or employee of the United States Government or of the government of the District of Columbia.*

Advisory Committee *– The Board is required to establish a standing public safety advisory committee. The Board can establish additional ad hoc committees, panels or councils as the Board determines necessary.*

Non-profit and non-political requirements on the Corporation - *The Corporation will not issue any stocks. No part of the income or assets of the Corporation shall inure to the benefit of any director, officer, employee, or any other individual associated with the Corporation, except as salary or reasonable compensation for services. The Corporation may not contribute to or otherwise support any political party or candidate for elective public office. The Corporation shall not engage in lobbying activities (as defined in section 3(7) of the Lobbying Disclosure Act of 1995 (5 U.S.C. 1602(7))).*

POWERS AND AUTHORITY OF THE CORPORATION

To carry out its duties and responsibilities under the law, general powers include:

- *Adopt and use a corporate seal.*
- *Have succession until the Corporation is dissolved by an Act of Congress.*

- *Regulate the way the Corporation conducts it general business.*
- *Exercise all powers specifically granted by the provisions of this subtitle, and such incidental powers as shall be necessary.*
- *Hold hearings, sit and act at such times and places, take such testimony, and receive such evidence as the Corporation considers necessary to carry out its responsibilities and duties.*
- *Obtain grants and funds from and make contracts with individuals, private companies, organizations, institutions, and Federal, State, regional, and local agencies.*
- *Accept, hold, administer, and utilize gifts, donations, and bequests of property, both real and personal, for the purposes of aiding or facilitating the work of the Corporation.*
- *Issue notes or bonds.*
- *Incur indebtedness.*
- *Spend funds in a manner authorized by the Board, but only for purposes that will advance or enhance public safety communications consistent with the Act.*
- *Establish a reserve fund.*
- *Expend reserve accounts.*
- *Take such other actions as the Corporation (through its Board) may from time to time determine necessary, appropriate, or advisable to accomplish the purposes set forth in the section.*

Powers to deploy and operate a nationwide public safety interoperable broadband network include:

- *Holding the license for the 20 MHz of spectrum.*
- *Take all actions necessary to necessary to ensure the building, deployment, and operation of a nationwide public safety interoperable broadband network in consultation with Federal, State, tribal, and local public safety entities, the Director of NIST, the Commission, and the public safety advisory committee. At a minimum the Corporation will*
    - *ensure nationwide standards for use and access of the network;*
    - *issue open, transparent, and competitive requests for proposals (RFP) to private sector entities for the purposes of building, operating, and maintaining the network;*
    - *encourage that such the RFPs leverage, to the maximum extent economically desirable, existing commercial wireless infrastructure to speed deployment of the network;*
    - *manage and oversee the implementation and execution of contracts or agreements with non-Federal entities to build, operate, and maintain the network.*
- *The Corporation shall ensure the safety, security, and resiliency of the network, including requirements for protecting and monitoring the network to protect against cyberattack;*

- *The Corporation will promote competition in the equipment market, including devices for public safety communications, by requiring that equipment for use on the network be:*
    - *built to open, non-proprietary, commercially available standards;*
    - *capable of being used by any public safety entity and by multiple vendors across all public safety broadband networks operating in the 700 MHz band; and*
    - *backward-compatible with existing second and third generation commercial networks to the extent that such capabilities are necessary and technically and economically reasonable.*
- *The Corporation will promote integration of the network with public safety answering points or their equivalent.*
- *The Corporation shall require deployment phases with substantial rural coverage milestones as part of each phase of the construction and deployment of the network. To the maximum extent economically desirable, such proposals shall include partnerships with existing commercial mobile providers to utilize cost-effective opportunities to speed deployment in rural areas.*
- *The Corporation can obtain grants from and make contracts with individuals, private companies, and Federal, State, regional, and local agencies to deploy and operate a nationwide public safety interoperable broadband network.*
- *The Corporation can hire or accept voluntary services of consultants, experts, advisory boards, and panels to deploy and operate a nationwide public safety interoperable broadband network.*
- *The Corporation can receive payment for use of the network capacity licensed to the Corporation; and network infrastructure constructed, owned, or operated by the Corporation; and take such other actions as may be necessary to accomplish the purposes set forth in this subsection.*

Other duties and responsibilities of the Corporation include:

- ***Network Policy:** Establishing the network policies by developing the RFPs with appropriate timetables for construction, coverage areas, service levels, performance criteria, and other similar in the construction of such networks; the technical and operational requirements for the network; the practices, procedures, and standards for the management and operation of such network; the terms of service for the use of the network; the ongoing compliance review and monitoring of the management, operation, use and training of network operators and users.*
- ***Existing Infrastructure:** The Corporation has the authority to enter into agreements to utilize, to the maximum extent economically desirable, existing commercial or other communications infrastructure; and Federal, State, tribal, or local infrastructure.*
- ***Maintenance and Operation of the Network:** The Corporation shall ensure the maintenance, operation, and improvement of the nationwide public safety interoperable broadband network.*

- ***Roaming on Commercial Networks*** *- The Corporation shall negotiate and enter into, as it determines appropriate, roaming agreements with commercial network providers to allow the nationwide public safety interoperable broadband network to roam onto commercial networks and gain prioritization of public safety communications over such networks in times of an emergency.*
- ***Network Infrastructure and Device*** *- The Director of NIST, in consultation with the Corporation and the Commission, shall ensure the development of a list of certified devices and components meeting appropriate protocols and standards for public safety entities and commercial vendors to adhere to, if such entities or vendors seek to have access to, use of, or compatibility with the nationwide public safety interoperable broadband network.*
- ***Standards Setting*** *- The Director of NIST, in consultation with the Corporation, the Commission, and the public safety advisory committee, shall represent the interests of public safety users of the nationwide public safety interoperable broadband network before any proceeding, negotiation, or other matter in which a standards organization, standards body, standards development organization, or any other recognized standards-setting entity regarding the development of standards relating to interoperability.*
- ***Foreign Governments*** *- The Corporation shall not have the authority to negotiate or enter into any agreements with a foreign government on behalf of the United States.*
- ***U.S. Mail*** *- The Corporation may use the United States mails in the same manner and under the same conditions as the departments and agencies of the United States.*

CONSULTATION WITH STATE AND LOCAL GOVERNMENTS

In the development of RFPs and carrying out the duties and responsibilities established under the Act, the Corporation shall consult with regional, State, tribal, and local jurisdictions regarding the distribution and expenditure of any amounts required to carry out the policies established above, including: construction of an Evolved Packet Core and any Radio Access Network build out; placement of towers; coverage areas of the network, adequacy of hardening, security, reliability, and resiliency requirements; assignment of priority to local users; assignment of priority and selection of entities seeking access to or use of the nationwide public safety interoperable broadband network; and training needs of local users. The consultation shall occur between the Corporation and the single officer or governmental body designated by each State to certify in its application for grant funds.

> ***[NOTE: The Public Safety Alliance has requested that S. 911 be amended to require "coordination" with state and local government instead of "consultation".*** *The PSA believes that agency coordination across jurisdictions (local, tribal, state, and federal) and close oversight of construction, operation, and funding are essential to building out the broadband network, which is why the PSA supports language in S. 911 that establishes the governance structure of a new independent nonprofit Corporation. The PSA*

*strongly believes, however, that public safety must hold majority representation on the Board of Directors of the new Corporation. This framework must ensure there is a requirement for state and local coordination with the new Corporation but this coordination requirement must not impede the build out of the network. The governance of the new Corporation must be transparent and held accountable to build out the nationwide network and ensure interoperability. Chief Jeff Johnson, Answers to Questions for the Record for House Energy and Commerce Subcommittee on Communications and Technology Hearing titled "Creating an Interoperable Public Safety Network." (May 25, 2011)***]**

S. 911 authorizes the Corporation to collect fees for network use, lease of network capacity, and lease of network equipment and infrastructure.

- ***Network User Fee** – The Corporation is authorized to collect a user or subscription fee from each entity, including any public safety entity or secondary user, that seeks access to or use of the nationwide public safety interoperable broadband network.*
- ***Network Capacity Lease Fee** – The Corporation is authorized to collect a fee from any entity that seeks to enter into a covered leasing agreement. The secondary user may access to network capacity on a secondary basis for non-public safety services; and the spectrum allocated to such entity to be used for commercial transmissions along the dark fiber of the long-haul network of such entity.*
- ***Network Equipment and Infrastructure Lease Fee** – The Corporation is authorized to collect a fee from any entity that seeks access to or use of any equipment or infrastructure, including antennas or towers, constructed or otherwise owned by the Corporation.*
- ***Fee Amount** - The total amount of the fees assessed for each fiscal year shall be sufficient, and shall not exceed the amount necessary, to recoup the total expenses of the Corporation in carrying out its duties and responsibilities of the Corporation for the fiscal year involved.*
- ***Reinvestment of Funds** - The Corporation shall reinvest amounts received from the assessment of fees in the nationwide public safety interoperable broadband network by using such funds only for constructing, maintaining, or improving the network.*

S. 911 also requires the Comptroller General of the United States to conduct annual audits of the Corporation. The audit report is required to be submitted to appropriate committees of Congress; the President; and the Corporation.

The Corporation is required to submit and annual report to the appropriate committees of Congress. The report is required to include a comprehensive and detailed report of the operations, activities, financial condition, and accomplishments of the Corporation; and such recommendations or proposals for legislative or *administrative action as the Corporation deems appropriate. The directors, officers, employees, and agents of the Corporation shall be available to testify before the appropriate committees of the Congress with respect to the report; the report of any audit made by the Comptroller General; or any other matter that such committees may determine appropriate.*

S. 911 authorizes the Commission to adopt rules, if necessary in the public interest, to improve the ability of public safety networks to roam onto commercial networks and to gain priority access to commercial networks in an emergency if the public safety entity equipment is technically compatible with the commercial network; the commercial network is reasonably compensated; and such access does not preempt or otherwise terminate or degrade all existing voice conversations or data sessions.

S. 911 Prohibits the Corporation from offering commercial telecommunications services to directly to consumers. The section however does not prohibit the Corporation and a secondary user from entering into a covered leasing agreement. The Corporation is not limited from collecting lease fees related to network equipment and infrastructure.

VII. COST-BENEFIT ANALYSIS OF ALLOCATION

Excerpt: Ford, G. S., & Spiwak, L. J. (2011, March). Public Safety or Commercial Use? A Cost/Benefit Framework for the D Block. PHOENIX CENTER POLICY BULLETIN (26).

Preliminary analysis suggests that the 10 MHz D Block plausibly provides at least $3.4 billion more in social benefits if assigned to public safety rather than to commercial use. The lost auction revenue, we observe that the loss of auction revenues today is more than offset by the gain of higher auction revenues and lower public safety network deployment cost in the future. Thus, an auction of the D Block adds, rather than relieves, stress to the public budget.

Perhaps the most daunting, yet relevant, question regards the social benefits of "public safety." Such benefits are real but difficult to quantify and, absent immediate crisis, prone to be undervalued. If we faced another event like 9-11 or Hurricane Katrina, we believe the 20 MHz would be allocated to public safety immediately and the network fully funded in a week's time. Fortunately, we are not presently victims of such a crisis and, though the lack of crisis makes the spectrum allocation decision a more difficult one, this is a burden we welcome. For the moment, we choose to set aside the quantification of the benefits of an additional 10 MHz of spectrum for public safety, looking instead at the cost side of equation.

Spectrum is not homogeneous. Not only is the 700 MHz spectrum highly valuable because its technical properties are well-suited for mobile communications, including broadband Internet services, but for the public safety community the D Block has added value because it is contiguous to the PSB, which is already allocated to the public safety community. A contiguous block of 20 MHz of spectrum is substantially *more valuable than 20 MHz of nonadjacent spectrum. As noted above, a 10 MHz block of contiguous spectrum in the 700 MHz band is worth about $2 to $6 billion more than a non-contiguous block of the same size.*

While this value differential is estimated based on commercial use, much of this premium is based on the lower cost of deploying network for contiguous spectrum, which would likewise apply to public safety. Evidence suggests that the cost of the public safety network using 20 MHz of spectrum is probably about $10 billion. Andrew Seybold, a highly regarded wireless industry expert, suggests that expanding a 10 MHz public safety network to 20 MHz adds about 15% to 25% to network deployment costs. By this standard, the incremental cost of the additional 10 MHz is about $1.5 to $2.5 billion. Alternately, adding a non-contiguous block of 10 MHz of spectrum to the public safety network would cost about $5 to $7.5 billion in deployment costs. Assignment of the D Block to public safety, therefore, is likely to reduce the cost of the public safety network by around $4 billion in network deployment costs alone. Operational costs are likely to be lower as well, perhaps adding billions more to the savings. Moreover, the cost to deploy the 700 MHz band is much lower than other bands (some estimates are 70% lower than other bands). Thus, depending on what additional spectrum is provided to the public safety community if they do not receive the current 10 MHz block, the ultimate deployment costs could be substantially higher (though this differential may also apply to the commercial licensee). We leave a more sophisticated assessment of such costs to others, and assume here that the cost difference is $4 billion.

While we have not addressed the benefits of public safety's use of the additional 10 MHz of spectrum, which could be quite large, we can see that the contiguous spectrum premium of $4 billion is itself sufficient to offset the value of commercial assignment of an additional 10 MHz ($0.6 billion).

Even if the 10 MHz provided zero benefit in terms of enhanced public safety, then assignment of the D Block to public safety produces $3.4 billion in additional social value over and above the commercial value of the same block.

Notably, much of this value spread arises from the unique opportunity to create significant value by allocating a contiguous block of spectrum to public safety, and then doing so in the future for commercial use. This value is foregone by commercial allocation of the D Block today. While some may contest our estimates, it is necessary to account for the economic value arising from contiguous spectrum.

VIII. JOB CREATION (100,000 NEW JOBS)

Excerpt: Shapiro, Robert J. and Aparna Mathur. "The Contributions of Information and Communication Technologies To American Growth, Productivity, Jobs and Prosperity." September 2011. Telecommunications Industry Association. SONECOM.

The $10 billion proposal to fund the development and initial deployment of a nationwide wireless broadband data and communications network for public safety agencies would lead to the creation of an estimated 100,000 new jobs in Information and Communication Technologies (ICT) industries and, over time, produce indirect or spillover benefits of an estimated $4 billion to $8 billion per year.

Based on the current use of labor and capital by ICT companies and prevailing wages, nearly $8 billion of the initial funding would go to salaries, sufficient to produce some 74,000 new ICT jobs with average compensation of $107,229 per-worker. In addition, the remaining, nearly $3 billion in new capital investments would support some 20,000 additional jobs.

Analysts calculate that the new network and its technologies could increase the productivity of police and fire agencies by at last 1 percentage point per year, producing direct efficiency savings of nearly $2 billion per year. The indirect benefits from a nationwide public safety network could total another $2 billion to $6 billion per-year.

IX. WHY PUBLIC SAFETY NEEDS MORE THAN 10 MHZ

Excerpt: Rysavy, Peter. "Public Safety Spectrum." July 2011.

While commercial operators can design their networks for typical densities of mobile users, emergency situations can result in needing to support extremely high densities of public safety workers. For this reason alone, the public-safety network has to have as high a capacity as possible. The network must have at least 20 MHz of spectrum. Anything less could lead to catastrophic consequences due to applications performing unreliably or failing completely.

The consequence of insufficient spectrum is restricted capacity, which combined with high demand, causes network congestion. For applications, this means sluggish behavior or outright failures.

Consequences of such congestion are not just slower performance but also application failures. Most communications protocols implement timeouts on their operations, including Transmission Control Protocol (TCP) itself, the packet-transport protocol used in the Internet to provide reliable end-to-end delivery. With large delays or dropped packets, communications protocols attempt to deliver data reliably, but at some level of congestion, they can no longer cope properly, and applications will either indicate a failure, or worse yet, require an application or full-system restart.

Beyond needing 20 MHz just to satisfy bandwidth requirements, there are compelling reasons for providing Public Safety 20 MHz of contiguous spectrum.

- *LTE is spectrally more efficient operating in 20 MHz channels than 10 MHz channels. In other words, the network can deliver more bits per second using a 10 MHz radio channel (10 MHz down, 10 MHz up) than in two 5 MHz radio channels.*
- *Using non-contiguous radio channels will significantly increase the cost of the radio access network due to the need for additional radios and antennas.*
- *Adding spectrum later in a non-contiguous manner will result in devices in the field likely not being able to take advantage of the new spectrum.*

X. WHAT HAPPENS IF D BLOCK IS NOT ALLOCATED

Excerpt: Ford, G. S., & Spiwak, L. J. (May 2011). Re-Auction of the D Block: A Review of the Arguments. PHOENIX CENTER FOR ADVANCED LEGAL & ECONOMIC PUBLIC POLICY STUDIES.

Many proponents of a D Block re-auction focus exclusively on the potential auction revenues from the block. Others appear to believe the auction will somehow fund the entire (or at least a good chunk of the) public safety network. In these tough financial times, it is difficult to criticize anyone looking for revenues or cost savings. However, it is essential to consider the full financial effects of the allocation options, not simply those implications favoring one option or another.

First, the claimed $3 billion in revenue from a D Block re-auction is too rosy an expectation. Statistical analysis of historical auctions indicates that a 10 MHz block of spectrum in the 700 MHz band must be unencumbered to produce $3 billion in revenues. Yet, the FCC's National Broadband Plan envisions a number of significant encumbrances on any reauction of the D Block which have substantially reduced auction revenues in the past. (In 2008, the D Block failed to secure a minimum bid at auction of $1.3 billion due to onerous encumbrances, creating the stalemate among lawmakers and policymakers we are faced with today over this block of spectrum.)

Re-auction of the D Block will increase government spending on the public safety network and reduce future auction revenues by far more than the re-auction may generate in revenues.

Second, the re-auction of the D Block will under no circumstances come close to fully funding a public safety network. A nationwide public safety network is expected to cost about $10 to $13 billion. Even if a re-auction of the D Block did bring in $3 billion of revenues, it offsets only about one quarter of the public safety network's cost. The D Block re-auction offers no other mechanism by which to generate funds for the remaining network construction and operating costs.

Finally, we discuss the potential broader adverse market effects of a D Block re-auction. The evidence indicates that the public safety community needs a full 20 MHz of spectrum. If the D Block is assigned to commercial use, then an additional 10 MHz for public safety must be obtained from either future spectrum assignments or the *capacity-equivalent thereof obtained via burdensome public safety encumbrances on commercial spectrum. This alternate block of spectrum will not be contiguous to the Public Safety Broadband ("PSB") Block, which has the effect of increasing the deployment cost of the public safety network by an estimated $4 billion relative to the D Block assignment.*

A commercial assignment of the D Block also has the potential of frustrating the creation of contiguous blocks of spectrum for future auctions, thereby substantially reducing auction revenues. Moreover, filling the public safety spectrum shortage with public safety obligations on all commercial providers could substantially reduce future auction revenues.

Based on an econometric analysis of the more recent spectrum auctions in the United States, if the FCC auctioned the D Block on a truly unencumbered basis, then we could expect the auction to generate revenues in the range $1.3 to $3.3 billion. However, the re-auction of the D Block is not unencumbered. The Commission has made clear that it intends to impose costly requirements on any re-auction of the D Block.

While the agency hopes for a "voluntary" public-private partnership, it nevertheless hedges, advancing a set of rules by which the D Block will be auctioned. These rules include the following:

- *D Block licensee(s) must use a nationally standardized air interface [to] ensure that the D block will be technically capable of supporting roaming and priority access by public safety users of the neighboring public safety broadband block;*

- *D Block licensee(s) are required to provide such roaming and priority access to public safety users;*

- *D Block licensee(s) must develop and offer devices that operate both on the D Block and the neighboring public safety broadband block; and*

- *[D Block licensee(s)] should be subject to commercially reasonable build out requirements.*

A network suitable for public safety also requires both higher technical standards and a larger footprint than does a strictly commercial network. And, logically, with such increased requirements comes higher network deployment costs, and, in turn, with higher deployment costs comes a lower auction value for the spectrum.

Former FCC Chairman Reed Hundt, who was serving as the President of potential D Block bidder Frontline Communications, conceded "the costs necessary to reach only a few additional users would entail a vastly disproportionate additional cost." Likewise, Verizon testified that the build out requirements were too "costly" and Qualcomm testified that the build out requirements were "too onerous", going so far as to note *that these requirements were "far more expensive than any of the current [commercial] networks."*

The new D Block licensee would be required to take on cost-increasing mandates including: (1) the use of a Commission-selected air interface; (2) the mandate to develop and offer devices that operate both on the D Block and the PSB Block; and (3) the requirement to build out the network on the agency's timetable. All of these requirements could increase deployment costs, thereby reducing the auction value of the D Block.

Public safety obligations of the first auction attempt reduced the value of the spectrum by 86% and, as discussed above, the FCC's reauction plan embraces similar encumbrances.

A reauction of the D Block could produce less than $1 billion in revenue and is unlikely to exceed $2 billion in the best plausible scenario.

XI. CONCLUSION

Allocating the D Block to public safety for the build-out of a nationwide, interoperable and mission critical-grade public safety broadband network will fundamentally alter the way first, second and situational responders plan, respond and react to disasters of all proportions. For the first time in decades, it will put leading edge technology into the hands of those individuals who are called on every day to put their lives on the line for the safety and security of the American public.

This paradigm shift has not gone unnoticed in the minds of scholars, public safety professionals, legislators, corporations specializing in public safety communications products and services, who have all written prodigiously on this subject. This report is comprised of selected sections of these manuscripts. Our belief is that the passages will help highlight key points in order to give the reader a granular, and ultimately more comprehensive understanding of the issue at hand. In order to give context to the selected passages, each of the papers are reproduced in their entirety, which can be found in the appendix of this binder. A number of other supporting materials not highlighted in this packet which speak to the need for additional spectrum for the public safety community can also be found in the appendix.

The Contributions of Information and Communication Technologies To American Growth, Productivity, Jobs and Prosperity[1]

Robert J. Shapiro and Aparna Mathur

I. Executive Summary

This study examines the role and impact of information and communications technologies ("ICT") in the American economy, and evaluates the likely effects of several current policy proposals and choices that involve ICT. This study includes both the reviews of the existing literature in this area as well as new analysis of the economic impact of ICT. Our critical findings include the following:

The Role of ICT in the American Economy

- In 2009, ICT firms contributed about $1 trillion to U.S. GDP, or 7.1 percent of GDP. This total includes nearly $600 billion in direct contributions from their own operations and more than $400 billion in indirect contributions through the benefits other sectors derived from the use of ICT.

- ICT companies accounted for 3,535,000 jobs in 2009. While total ICT employment declined since 2000, average compensation has risen sharply. In 2009, the compensation of full-time ICT employees averaged $107,229, 80.6 percent higher than the average for all full-time workers. From 1991 to 2009, average compensation in the ICT industry increased 162 percent, the fastest income gains of any U.S. industry.

- From 1991 to the present, ICT firms have contributed directly an average of $577 billion per-year in value-added to America's GDP. These direct contributions were equivalent to nearly one-third of the value-added provided by all manufacturing.

- According to an analysis by Federal Reserve economists, the use of ICT accounted for 28 percent of all U.S. productivity gains from 1995 to 2001, capital investments in those technologies explain another 34 percent of those gains, and changes in the organization of firms and worker training in response to ICT innovations accounted for another 10 percent of productivity gains.

- From 1991 to 2009, full-time ICT workers experienced larger wage and compensation gains than workers in any other sector, and the average compensation of ICT workers in 2009 was more than 80 percent higher than the average for all other private-sector workers.

[1] The authors gratefully acknowledge the research assistance of Jiwon Vellucci and Lisa Hamilton, and financial support for our research from the Technology Industry Association. The views and analyses are solely our own.

- ICT's direct contributions to GDP have increased nearly 25 percent since the 1990s, growing from 3.4 percent of GDP per-year in 1991-1993 to an average of 4.2 percent per-year over the years 2005-2009 – gains unmatched by any other industry.

The Impact of Policy Proposals that Rely on ICT Investments

The President's proposal to invest $10.7 billion in a nationwide public safety network

- The President's proposal to fund the development and initial deployment of a nationwide wireless broadband data and communications network for public safety agencies would lead to the creation of an estimated 100,000 new jobs in ICT industries and, over time, produce indirect or spillover benefits of an estimated $4 billion to $8 billion per year.

- Based on the current use of labor and capital by ICT companies and prevailing wages, nearly $8 billion of the initial funding would go to salaries, sufficient to produce some 74,000 new ICT jobs with average compensation of $107,229 per-worker. In addition, the remaining, nearly $3 billion in new capital investments would support some 20,000 additional jobs.

- Analysts calculate that the new network and its technologies could increase the productivity of police and fire agencies by at last 1 percentage point per year, producing direct efficiency savings of nearly $2 billion per year. The indirect benefits from a nationwide public safety network could total another $2 billion to $6 billion per-year.

Investments of $3.4 billion in a "Smart Electricity Grid" under the 2009 Recovery Act

- These investments should directly produce nearly 30,000 new jobs. If the funding becomes seed money and an ICT-based Smart Grid is developed and deployed, analysts estimate the net economic benefits could range from $48 billion to $76 billion per year.

- If the Smart Grid can reduce power outages by 20 percent, as predicted by the National Energy Technology Laboratory, it would save $20 billion per year. A Smart Grid also would virtually eliminate large-scale power blackout which now cost the economy $10 billion per-incident.

- Smart Grid monitoring of energy flows to large customers would generate benefits estimated at $10 billion per-year. Continuous, ICT-based monitoring also should reduce operational and maintenance costs by at least 10 percent, or another $2.5 billion per-year.

- The Smart Grid also should reduce transmission and delivery losses by at least 10 percent, generating $2.5 billion in annual benefits, and cutting the costs of transmission congestion by 10 percent, a reasonable target, should save another $2 billion per year.

- The Smart Grid also would allow utilities to eliminate or defer some large capital investments in centralized generating plants, substations and transmission and distribution lines, reducing their costs by an estimated $2 billion to $6 billion per-year.

Proposals to reduce the lower corporate tax burden

- Lowering the corporate tax burden by 10 percent would increase investments in ICT by nearly $71 billion over several years, which in turn should raise productivity and total business spending on wages, salaries and other compensation by nearly $450 billion.

- The additional ICT investments spurred by this lower corporate tax burden would produce indirect benefits or spillovers in other industries that would increase the value-added produced across the economy by nearly $450 billion.

- This reduction in the tax burden on businesses would generate an estimated $990 billion increase in all capital investments, with the largest increases occurring in manufacturing and utilities, mining and oil and gas exploration, finance and insurance, and real estate, rentals and leasing.

- Over several years, these increases in business investment and productivity would drive associated increases in workers' compensation, sufficient to cover wage gains averaging nearly $5,500 per-worker across the economy, or alternatively, some 6.8 million new jobs, or some combination of higher wages and additional jobs.

- The additional investments in ICT spurred by the reduction in the corporate tax burden would produce spillovers that would increase the value-added produced across the economy by $447.9 billion.

II. Introduction and Summary

For as long as organized economies have existed, human knowledge has been the basis for most economic value. From farmers millennia ago who first figured out the benefits of regularly watering and weeding their crops, to modern agribusiness applying advanced technologies to tend and harvest thousands of acres of genetically-modified foods, every economic advance has involved the use of new ideas. In recent times, the broad application of information and communication technologies (ICT) has accelerated this process. As a result, ICT industries have come to play a disproportionate role in the growth and continuing development of the U.S. economy. This study analyzes and assesses that role.

The ICT sector encompasses four sub-industries: computer and electronic products; publishing (including software); information and data processing services; and computer systems design and related services. Over the last generation, these distinctive ICT goods, services and systems have diffused across the American economy. This process of diffusion reflects the growing direct demand for the products of ICT companies, and as a result, the inflation-adjusted value-added created by ICT companies expanded from 3.4 percent of GDP in 1991 to 4.2 percent of GDP in 2009.[2] This means that ICT firms directly contributed about $600 billion to U.S. GDP in 2009. Over the same 18-year period, the average annual compensation of full-time ICT workers increased from just under $41,000 to more than $107,000, the fastest wage and

[2] See Table 2, below.

compensation gains of any sector. The average compensation of ICT workers is now more than 80 percent higher than the $59,400 average for all other private-sector American workers.[3]

ICT is broadly understood to be comprised of genuine “general purpose” or enabling technologies that can be adopted and adapted by every other industry. The data bear out this view: In the 1990s, investments in ICT by other industries grew 10 times faster than their investments in any other inputs. By the mid-to-late 1990s, economists began to seriously assess the effects of these investments Two early studies found that the use of ICT by other industries contributed one-sixth of average annual GDP growth in the years 1990-1995/6.[4] The estimates of ICT’s impact on U.S. growth in the later-1990s are even greater: Studies trace half or more of U.S. gains in productivity in those years to ICT.[5] In the last decade, economists have focused on the “spillovers” or “positive externalities” associated with the application of these ICT investments, from e-commerce to ICT-based management of supply chains.

This study is part of this long line of analyses assessing the direct and indirect economic benefits of ICT. Here, we use the 2009 Input-Output tables of the Bureau of Economic Analysis (BEA) to trace the flows of goods and services between ICT industries and all other industries, in order to estimate the value which each industry derived from its ICT investments. For example, we find that 3.1 percent of the total output of U.S. manufacturing in 2009 can be traced to ICT investments, as well as 4.3 percent of the output of the information sector, 4.0 percent of the output of management consultants, and 2.4 percent of the output of professional, scientific and technical services. Across industries, the benefits from ICT investments added over $400 billion to GDP in 2009, on top of nearly $600 billion in direct economic activity by ICT firms.

All told, therefore, the ICT sector was responsible, directly or indirectly, for a little more than $1 trillion in value-added in 2009, or 7.1 percent of U.S. GDP in that year.

Given the disproportionate economic impact of ICT industries, we also examine several policy proposals that could affect both the direct demand for ICT and the use of ICT by other industries. We focus on three initiatives – proposals to fund an ICT-based data and communication network for public safety agencies; funding approved in the 2009 stimulus Act to support the development of an ICT-enabled smart electricity grid; and a 10 percent reduction in the corporate tax burden. All three initiatives could provide significant economic benefits.

The two funding proposals will (smart electricity grid) or may (public safety network, not yet adopted) produce direct job creation in the ICT sector as well as large spillover effects in other industries. The President’s recent proposal to commit $10.7 billion to develop and deploy a nationwide wireless broadband data and communications network for public safety agencies should enable police, fire personnel and other first-responder agencies to improve the quality of their services and reduce operational costs. It also would lead to the creation of an estimated 100,000 new jobs in ICT industries alone and, over time, potential spillover benefits of some $4 billion to $8 billion per-year. Similarly, $3.4 billion allocated under the 2009 stimulus Act for investments in the digital-based modernization of the nation’s electricity grid, in order to create a

[3] See Table 3, below.
[4] Jorgenson and Stiroh (1999); Oliner and Sichel (2000).
[5] See footnotes 11, 12 and 13.

"Smart Grid," also should produce a stream of economic benefits. These expected benefits include a greater capacity to maintain the national electricity grid, detect and prevent outages and other problems throughout the grid, reduce both utility costs and energy consumption, and spur the deployment of more energy-efficient "smart buildings" and "smart appliances." The 2009 funding should directly produce nearly 30,000 new jobs directly. If this funding becomes the seed money for the full development of an ICT-based Smart Grid, the net economic benefits could range from $48 billion to $76 billion per-year.

Finally, a 10 percent reduction in the effective corporate tax rate would have large positive effects on ICT investment and business investment generally, assuming that the revenues costs would be offset by spending reductions or other revenue increases. A 10 percent reduction in the tax burden for all U.S. industries would produce an estimated $990 billion increase in business investment over several years, including nearly $71 billion in additional investments in ICT goods and services. After several years, those increases in ICT capital would produce an additional $448 billion in annual GDP. Based on how various industries have responded to increases in their ICT capital stock, these increases in ICT investment should produce significant gains for compensation and/or employment in every industry. If all of these benefits went to higher wages with no additional jobs, it would raise the average compensation of American workers after several years by $5,424, ranging from $836 per-worker in the accommodations and food service sector to $15,316 per-worker in the information industry.[6] Similarly, if all of the benefits of the additional ICT investments went to job creation, it would generate more than 6.8 million additional jobs after several years.

III. Innovation and Economic Growth and Productivity

Knowledge is the source of most economic value. When a company or country improves its underlying rates of growth and productivity, those improvements usually reflect the application of new ideas embodied in technological or organizational innovations. In the current period, many of those innovations involve ICT or organizational changes designed to enable firms to take advantage of their ICT investments.

The natural factors involved in economic activities – fuels and minerals, animal and plant life, land – all have been available for a very long time. Over time, however, innovators have developed and applied successive generations of new ideas about how best to use and combine those factors. The value of a microchip, fiber optic cable or supercomputer is countless times greater than the value of the minerals and other natural elements that comprise them, and that difference reflects the economic value of the many generations of ideas and innovations which now enable us to transform those elements into these technologies.

How well and how quickly a nation's enterprises develop, adopt and apply economic innovations, therefore, significantly influences that nation's overall growth, productivity and wage progress. Economists have established that innovation plays a larger role in economic progress than increases in capital investment or even improvements in the skills and education of workers. Beginning with the research of Nobel laureate Robert Solow in the 1950s, studies have established that the development and adoption of innovations is the single most powerful

[6] See Table 9, below.

determinant of a nation's underlying rate of economic growth. For example, Solow and others found that 30 percent to 40 percent of the economic gains achieved by the United States in the 20th century can be traced to economic innovation.[7] These innovations encompass not only new technologies, materials and production processes, but also new ways of financing, marketing and distributing goods and services, and new approaches for organizing a business and managing the workplace. By contrast, increases in the American economy's capital stock can explain only 10 percent to 15 percent of those gains, while another 20 percent can be traced to improvements in the education and skills of American workers.

Furthermore, the importance of innovations apparently has increased in recent times. One recent study used a version of Solow's growth accounting to examine the impact of innovation from 1973 to 1995, compared to 1996 to 2003.[8] The authors found that the impact of innovation on U.S. growth increased from 25 percent in the first period to 35 percent in the second.[9] This conclusion is consistent with recent work by researchers at the Federal Reserve Board of Governors, who found that since 1995, for the first time on record, U.S. businesses have invested as much in these idea-related intangibles[10] – about $1 trillion a year in the early years of this decade – as they do on plant, equipment and other traditional, tangible forms of investment.[11] The authors of this paper also found that U.S. business spending on long-lasting, knowledge capital grew faster than any other type of business or personal spending. Finally, the study traced more than four-fifths of the gains in U.S. productivity achieved in the latter-1990s to the development and use of new technologies and other innovations.

The Role of ICT Innovation

Innovation in recent years, perhaps more than in most periods, has been concentrated in a few areas, especially information and communications technologies. The Federal Reserve study of intangible investment found that the development of new ICT accounted for 28 percent of U.S. productivity gains from 1995 to 2001, capital investments in those technologies explained another 34 percent, and changes in the organization of firms and worker training in response to these innovations accounted for another 10 percent. These findings were the latest in a long line of analyses of the impact of ICT, reaching back now nearly two decades. In a 1999 study, for example, Harvard economist Dale Jorgenson and Kevin Stiroh from the Federal Reserve Bank of New York tracked the extraordinarily rapid adoption of computers by businesses and households in the 1990s, as the price of computers fell dramatically.[12] Throughout that decade, business investments in computers grew 28.3 percent per-year; household computer purchases increased even faster, by 37.3 percent per-year; and computer services to firms and households grew 20 percent per-year. These growth rates were 10 to 18 times the average annual growth for other inputs. By 1996, U.S. businesses spent nearly $180 billion annually on new computers, and consumers spent an additional $170 billion.

---

[7] Solow (1956); Solow (1957); Denison (1962).
[8] Van Ark, , *et. al.* (2009).
[9] They divided up growth factors and found that the contribution of "multifactor productivity," largely a proxy for the development and application of innovations, increased from 25 to 35 percent.
[10] This broad category includes including investments in software programs and databases, scientific and non-scientific R&D, new-product development costs by service firms; advertising and market research to create brands; the development of new business models and corporate cultures; and expenditures on firm-specific training.
[11] Corrado, Hulten, and Sichel (2004)
[12] Jorgenson and Stiroh (1999).

This broad adoption of computers and their software enhanced the economic impact of the efficiencies and new capacities associated with their use. The Jorgenson-Stiroh study found that business use of computers added 0.26 percentage-points per-year to U.S. growth over the 1990-1996 period, while household purchases of computing equipment and services contributed an additional 0.13 percentage-points to growth, each year. Together, these two dynamics accounted for nearly one sixth of the average annual 2.4 percent growth in GDP in these years.[13]

Another well-known study by Stephen D. Oliner and Daniel E. Sichel measured ICT's contribution to growth of information and communications technologies over two periods: 1974 to 1990 and 1990 to 1995.[14] Over both periods, real growth averaged about 3 percent per-year; and the authors traced 0.25 percentage-points of that to computer hardware. They further found that software contributed 0.1 percentage-points to growth per-year in the first period and 0.25 percentage-points per-year in the second period, and that communications equipment contributed another 0.1 percentage point per-year over both periods. All told, ICT capital accounted for about 0.5 percentage points of U.S. annual growth over both periods, or again about one-sixth of our growth. Moreover, these ICT contributions to growth surged in the second half of the 1990s: The authors estimate that this contribution more than doubled to an average of 1.1 percentage-points per-year over the years 1996-1999 as the growth of the real stock of ICT capital accelerated. They also calculated that nearly half of the acceleration in labor productivity, from gains of 1.5 percent per-year in the first half of the 1990s to gains of 2.6 percent per-year in the second half of the decade, can be traced to rapid growth of ITC capital.

ICT's total contribution to U.S. growth is even greater than these studies suggest, however, because the studies do not take account of the spillover effects of ICT on growth in other industries. One characteristic of ICT capital which distinguishes it from traditional capital investment is the wide diffusion of ICT hardware and software across the economy and the broad range of their applications. Manufacturing companies, for example, operate computer-integrated systems that link together design, production, and management activities to produce more efficient use of resources. Information and communication technologies also enable firms to interact with other businesses faster and more efficiently, directly or through their supply chains. Some researchers evaluating the impact of ICT have focused on these network effects.[15] ICT-based networks, then, not only facilitate communication between firms; they also help streamline production processes and lower transaction costs. Therefore, another feature that distinguishes ICT capital from other traditional inputs is that ICT capital can generate considerable positive "externalities" or economic effects.

Network externalities, which occur when the efficiency or value of a product or service increases as the product or service is adopted by more users, is a signature feature of ICT.

---

[13] GDP growth can also be expressed as the sum of the contributions of increases in capital services, consumers' durable services, labor inputs, and the TFP residual. The contributions of capital and consumers' durables can be decomposed into computer and non-computer components. Through the 1990s, computers were responsible for nearly 20 percent of the contribution of capital inputs to growth and 14 percent of the contribution of consumers' durables services. Taken together, these computer inputs contributed 0 .16 percentage points to the output growth for 1990-1996. These sources of growth are a direct result of substitution toward relatively cheap computers.

[14] Oliner and Sichel (2000).

[15] For example, Bresnahan (2001); Brynjolfsson and Hitt (2000); and Inoue (1998).

Economists further distinguish between direct and indirect network effects.[16] The direct version occurs from an increase in the number of users of an ICT product or service, as when growing numbers of PC owners increase the value of each owner's PC. The indirect network effect occurs from the development of applications, as when the growing number of users of Windows increases the usefulness of both PCs and Windows to each user, or more recently in the I-Phone and its many thousands of applications. The direct and indirect network effects of ICT, therefore, can have a significant impact on the diffusion and usage of that capital.

In addition to these network externalities associated with ICT, ICT can produce another type of externality, so-called knowledge spillovers or learning effects. The adoption of ICT typically produces or involves innovations in the production process and organizational changes.[17] As the noted Berkeley economist Paul Romer wrote a generation ago, the knowledge that enables a firm or industry to successfully adopt these advanced technologies tends to naturally spread or spill over to other firms and industries.[18] Therefore, in assessing the indirect economic benefits associated with ICT, we need to take account of the interdependence of firms in different industries and their inter-industry transactions.

A 2002 study measured these ICT spillovers using data for 42 industries from the national Input-Output tables over the period 1984 to 2000.[19] The authors found that industries with more transactions with ICT-intensive industries have larger ICT spillover effects. One striking finding is that the computerization of an industry's suppliers and customers reduces the industry's average costs, a clear example of a positive externality from ICT. Table 1, below, shows the average return received and average return generated by the 42 industries from their ICT capital stock and its spillovers. The first column shows the average returns to an industry from a one dollar increase in the ICT capital stock of other industries. Banking and security, wholesale trade, and business services derived the greatest returns from their transactions with ITC-intensive-industries; and among manufacturing industries, industrial machinery and equipment, and electronic and other electric equipment received the greatest benefits from these interactions. The common characteristic of the industries deriving the greatest benefits is that they are themselves intensive users of ICT capital. These findings suggest that the returns to an industry from these inter-industry transactions depend on an industry's own ICT capital.

The second column in the table shows the benefits to an industry of interacting with other industries that have ICT stocks, expressed as the returns that a one dollar increase in an industry's ICT capital stock generates *for other industries*. If a firm's suppliers have large ICT investments, the computerization of those suppliers will have positive spillovers for the firm, called "backward linkage." At the same time, the computerization of a firm's customer industries also produces spillovers for the firm, called "forward linkage." Backward and forward linkages from ICT investments reduce the average and variable costs for any industry, expressed as a return achieved by firms from interacting with its supplier and customer industries.

The results suggest that industries which receive large returns from their interactions – large spillover benefits -- also generate large returns from their own ICT for other industries.

[16] Katz and Shapiro (1985).
[17] Brynjolfsson and Hitt (2000).
[18] Romer (1986).
[19] Mun and Nadiri (2002).

The industry that generates the largest returns for other industries in this way is business services. For example, a $1 increase in the ICT investments by other industries generates an additional return – through lower costs -- of 4.8-cents for firms providing business services; and a $1 increase in the ICT investments by business services generates an additional return of 4.7-cents for other industries. The analysis also shows that some industries receive more benefits from interacting with ICT-intensive industries than their own ICT generates for other industries. For example, the bank and security industry receives four times the benefits from its interactions with other industries than its own ICT capital generates for other industries. In general, industries that receive greater returns than their ICT capital stocks generate for other industries are mainly service industries such as bank and security, wholesale trade, and communication.

Table 1: Average Returns Received and Generated From $1 Increase in ICT Capital Stock, By Industry, 1984-2000[20]

Industry	Average Return Received	Average Return Generated

Other services	0.014	0.024

Other research has focused on estimating the benefits of ICT for specific sectors or business lines. For example, a 2000 study analyzed the benefits of ICT for emergency response or 911 systems.[21] During the 1990s, many municipalities adopted "Enhanced 911" systems which used ICT to link automatic caller-identification to a database of address and location information, in an effort to shorten the time required for emergency responses. Using data from Enhanced 911 systems in counties in Pennsylvania from 1994 to 1996, the authors found that E-911 systems increased short-term survival rates for patients with cardiac diagnoses by about one percent. Similarly, the use of ICT enables hospitals to remotely monitor their intensive care units, feeding video, audio, and vital data to a single interface that allows doctors, nurses, and assistants to monitor many beds in multiple hospitals at once. By improving patient surveillance, two ICUs in Norfolk, VA, reduced deaths by 27 percent in the first year and cut their costs per-ICU case by 25 percent.[22] Other studies have documented a similar role for ICT in improving the affordability, safety, capability and efficiency of air transportation.[23]

In general, the ICT sector provides a wide range of benefits to different industries depending on how the technologies are applied and the characteristics of the adopting organization. With the broad adoption of ICT by retail businesses, for example, e-commerce transactions have grown six times faster than total retail sales, providing large externality benefits. This growth has also generated externality benefits for consumers: One recent survey found, for example, that consumers save between 10 percent and 40 percent by buying contact lenses over the Internet, compared to the prices charged by optometrists.[24] Online retail should continue to grow, in part because the longer people are online, the more likely they are to make more online purchases. While e-commerce still represents a modest share of retail sales, it

[21] Athey and Stern (2002).

[24] Atkinson and McKay (2007).

accounts for a sizeable share of the total transactions in certain areas, with, for example, more than 20 percent of airline and other travel reservations occurring online.

IV. The Contributions of the ICT sector to GDP, Value-Added, Jobs and Compensation

The ICT sector – computer and electronic products, software and other publishing, information and data processing services, and computer systems design and services – has averaged double-digit growth for the past decade. From 1987 to 2008, the sector grew every year.[25] The recession years of 2001 and 2009 were the only times that ICT's value-added declined, driven by contractions in software and computer and electronics products. Table 2 shows the ICT sector's direct contribution to economic growth, employment, and incomes.[26]

Table 2: Contribution of ICT to U.S. GDP, Value-Added, Employment and Compensation, 1991-2009

Year	Value Added By ICT ($ millions)	Value Added as A Percent of GDP	Total Compensation By ICT ($ millions)	ICT Employment, Full-Time Equivalents	Average Compensation, Full-Time ICT Worker
1991	$203,829	3.4%	$172,258	4,207,000	$40,946
1992	$215,949	3.4%	$177,104	4,076,000	$43,450
1993	$227,404	3.4%	$185,636	4,081,000	$45,488
1994	$253,404	3.6%	$198,533	4,183,000	$47,462
1995	$275,859	3.7%	$208,887	4,242,000	$49,243
1995	$303,962	3.9%	$217,225	4,303,000	$50,482
1997	$343,181	4.1%	$234,466	4,415,000	$53,107

2008	$607,128	4.2%	$395,959	3,782,000	$104,696
2009	$599,797	4.2%	$379,056	3,535,000	$107,229

[25] Harris, *et al.* (2011).
[26] Bureau of Economic Analysis. Industry Economic Accounts: Gross-Domestic-Product-(GDP)-by-Industry Data. The compensation and jobs data before 1997 use the SIC classification of industries, while post-1997 uses NAICS data. Data on Full-time Equivalent workers are available only by SIC codes, and therefore the SIC-based series from 1991-1997 may not be perfectly comparable to the NAICs-based series from 1998 to 2009.

As Table 2 shows, ICT's contribution to GDP has risen nearly 25 percent since the 1990s, increasing from 3.4 percent of GDP in 1991-1993 to an average of 4.2 percent over the years 2005-2009. No other industry matches those gains. Over this period, ICT firms directly contributed an average of $577 billion per-year in value-added to GDP. Thus, ICT's direct contribution was equal to nearly one-third of the contribution of all manufacturing at 11.2 percent of GDP. From 2005 to 2009, GDP grew by about $4.2 trillion, from $9,951.5 billion to $14,119 billion; and ICT gains directly accounted for 4.0 percent to 4.5 percent of that growth.

ICT companies also accounted for 4.1 million to 4.5 million full-time jobs in the 1990s. ICT employment has declined gradually since 2001, but the average compensation of its workers has increased sharply. From 1991 to 2000, this average compensation more than doubled from $40,946 in 1991 to $83,375 in 2000. From 2000 to 2009, this average compensation rose another 29 percent from $83,375 in 2000 to $107,229 in 2009, even as average incomes for all Americans declined. From 1991 to 2009, average ICT compensation rose 162 percent, the fastest gains of any sector. As a result, the gap between the average compensation of ICT and other private-sector workers widened sharply, from 29.5 percent in 1991 to 80.6 percent in 2009. (Table 3, below) Counting only wages and salaries, the average weekly earnings of ICT employees in 2010 were $938.89 or nearly 50 percent higher than all private-sector employees.[27]

Table 3. Average Compensation, ICT versus All Other Private-Sector Workers, 1991-2009

Year	Average Compensation, Full-Time ICT Worker	Average Compensation, Full-Time Non-ICT Private-Sector Worker	Difference: Compensation Advantage of ICT Workers
1991	$40,946	$31,613	29.5%
1992	$43,450	$33,372	30.2%
1993	$45,488	$34,222	32.9%
1994	$47,462	$34,978	35.7%
1995	$49,243	$35,711	37.9%
1995	$50,482	$36,682	37.6%
1997	$53,107	$38,094	39.4%
1998	$67,824	$40,168	68.9%
1999	$75,876	$41,693	82.0%
2000	$83,375	$44,063	89.2%
2001	$81,252	$45,508	78.5%
2002	$82,004	$47,009	74.4%
2003	$85,970	$49,217	74.7%
2004	$90,686	$50,952	78.0%
2005	$94,473	$52,681	79.3%
2006	$97,934	$54,742	78.9%
2007	$103,349	$56,805	81.9%
2008	$104,696	$58,437	79.2%
2009	$107,229	$59,381	80.6%

[27] Bureau of Labor Statistics, ftp://ftp.bls.gov/pub/suppl/empsit.ceseeb2.txt.

We also can estimate the contribution of ICT investments to the output of other industries. To do so, we use BEA input-output tables.[28] BEA provides two types of these tables to measure linkages between industries. The first is called the Make table, with rows that show the value of each good or commodity produced by each industry and columns that distribute the output of each good or commodity across industries.[29] For example, the 2009 Make table shows that the "Farms" industry contributed 99.8 percent of total "Farms" commodities. The second table is the Use table, which shows the value of each commodity or good used in producing the output of each industry. Each column in the Use table sums to an industry's total output, while each row shows the value of each good or commodity that goes towards producing that output. For example, the 2009 Use table shows that the "Farms" industry used 12.3 percent of Farm industry commodities and less than 1 percent of Machinery industry commodities to produce total output of $299.1 billion.

To estimate the value each industry derives from ICT investments, we created an "Adjusted Make Table" that shows the share of each commodity's total output contributed by all other industries. Technically, we divide each element of the Make Table by its column total, which is the industry's total output of a commodity, and each element in the row shows the output of that commodity being produced by the industry. Therefore, the Adjusted Make Table shows the share of the total value of the commodity produced by each industry. Next, we multiply these values by those in the Use table. This gives us an industry-by-industry matrix in which each element shows the contribution of each industry to the total output of all other industries. From this matrix, we can isolate the spillovers or contributions of ICT industries to other industries.[30]

Table 4, below, shows, for example, that the output by information and services industries as well as several manufacturing industries depend particularly on ICT investments. ICT investments account for more than 4.3 percent of the total output of the information sector, more than 3.1 percent of the output of all manufacturing, and nearly 4.0 percent of the output of business management services. Moreover, this analysis also can measure spillovers from ICT by analyzing the flow of goods between the ICT industries and all other industries. We find that the ICT industries contributed $528.2 billion in value to other industries in 2009, or 3.74 percent of the total U.S. GDP of $14.1 trillion in that year. The public sector accounts for $128.6 billion of that total. Considering only the private sector, spillovers from ICT were responsible for $401.3 billion of the value produced by non-ICT industries. Moreover, this estimate is conservative, because it captures direct spillovers but not indirect ones that, for example, reduce costs in other industries.[31]

[28] Bureau of Economic Analysis. Industry Economic Accounts: Input-Output Accounts Data, http://www.bea.gov/industry/io_annual.htm.

[29] There are 65 industry and commodity groups. Each column corresponds to a specific commodity group and the column total is the total output of that commodity. Each row corresponds to a specific industry and shows the output of each commodity produced by that industry. Note that the industry and commodity groupings are titled the same.

[30] Note we show the ICT industries, such as computer and electronics product, publishing industries, and so on.

[31] Mun and Nadiri (2002).

Table 4: Spillover Effects of the ICT Sector On All Industries, 2009[32]

Industry	Use of ICT ($ millions)	Output* ($ millions)	ICT Share of Total Output
Agriculture, Forestry, Fishing	$847	$340,726	0.25%
Mining, Oil, Gas Exploration	$1,797	$349,233	0.51%
Utilities	$1,733	$392,461	0.44%
Construction	$13,809	$1,091,005	1.27%
Manufacturing	$141,115	$4,522,357	3.12%
Wholesale Trade	$10,591	$1,018,943	1.04%
Retail Trade	$14,363	$1,193,407	1.20$
Transportation and Warehousing	$3,605	$712,451	0.51%
Information	$51,429	$1,191,925	4.31%
Finance & Insurance	$43,049	$2,264,742	1.90%
Real Estate, Rental & Leasing	$8,340	$2,619,605	0.32%
Profess'al, Scientific, Tech. Services	$35,716	$1,514,926	2.36%
Management of Companies	$14,965	$378,177	3.96%
Administrative, Support, Waste Mgt	$15,362	$621,861	2.47%
Education	$5,879	$240,194	2.45%
Health Care & Social Assistance	$19,020	$1,705,157	1.12%
Arts, Entertainment & Recreation	$1,989	$209,568	0.95%
Accommodation & Food Services	$8,572	$718,869	1.19%
Other Services	$9,166	$559,502	1.64%
Total or Average	**$401,347**	**$21,645,109**	**1.93%**
Government	$126,811	$3,159,049	4.01%

Based on this analysis, we can measure ICT's total contribution to U.S. GDP and growth. As Table 4, above, shows, the industries deriving the greatest benefits from ICT are manufacturing, information, finance and insurance, and professional, scientific and technical services. Across the economy, these indirect effects from ICT investments added nearly $401.4 billion to U.S. GDP in 2009, on top of the $599.8 billion in value-added contributed directly by ICT companies in 2009. All told, therefore, the ICT industry contributed $1,001.1 billion to U.S. GDP in 2009, or 7.1 percent of total GDP. In addition, this analysis allows us to estimate the value derived by government from its use of ICT, which as noted came to $126.8 billion in 2009.

V. The Impact of Policy on Levels on ICT Investment and Innovation

The powerful impact of ICT on the performance of other industries increases the importance of policies that can affect their use of ICT. Here, we examine three such initiatives currently discussed in policy circles and analyze the ICT-related benefits generated in each case: 1) The range of economic benefits expected from proposed funding for an ICT-based national wireless public safety network; 2) the potential economic benefits from the proposed funding for an ICT-based reconfiguration of the nation's electricity grid into a "Smart Grid;" and 3) the impact of a 10 percent reduction in corporate taxes on ICT investments by various industries, and their impact on wage and employment gains.

[32] Total exceeds GDP, because outputs from one industry are inputs for other industries. Also, the contributions of ICT to each sub-industry in the manufacturing sector are presented in the Appendix (Table A-1).

The National Public Safety Network

Since taking office, the Obama administration has proposed a number of initiatives involving the intensive use of ICT to help address social and economic issues. One prominent example is the proposal in the President's current, FY 2011 budget for $10.7 billion to support the development and deployment of a nationwide wireless broadband network dedicated to public safety. The funds would go to create a wireless communications network for emergency service agencies across the country, including police, firefighters and emergency medical service personnel, to help them prevent or respond more efficiently and effectively to incidents that endanger people or property.

The proposed program should generate a range of economic benefits. To begin, the direct funding should create nearly 100,000 new jobs: A White House assessment and a separate study by Cisco (2009) concurred that the program and its funding would generate employment for network planners; laborers for laying and installing cable; technicians to build and install network devices, wireless access points, video surveillance cameras, gunshot detectors, and environmental sensors; and trainers for installation.[33] As the network is established, it would create more jobs for network administrators and managers, technical support staff, network analysts, project managers, and IT analysts. Based on the current use of labor and capital by ICT companies and prevailing wages, nearly $8 billion of the initial funding would go to salaries, sufficient to create about 74,000 new ICT jobs. In addition, the nearly $3 billion in new capital investments should support perhaps 20,000 additional jobs.

While a majority of the ICT investments would occur from public-sector agencies, and there are no analyses of the employment effects of ICT investments specifically by the public sector, we assume here that the new public-sector ICT investments would be allocated to capital and labor in the same proportions as in the ICT sector itself. With a capital-labor ratio of 0.32, approximately 25 percent of the total value of the capital and labor employed should go for capital investments. Therefore, about 75 percent of the total $10.7 billion invested in the public safety networks would be used for new ICT-related employment, or nearly $8 billion. At an average compensation per-worker of $107,229, those funds would produce the nearly 74,000 new jobs. If the investments in the public safety network are more capital intensive than we assume here, the employment gains could be less.

A wireless broadband network of public safety agencies also would generate substantial direct savings for law enforcement and other emergency personnel, and equally substantial indirect savings from the lives saved and property preserved. We cannot know precisely how great these savings would be. However, if the use of the new network and its technologies increases the productivity of police and fire agencies by 1 percentage point per-year – less than comparable innovations increased private-sector productivity – the direct efficiency savings would be nearly $2 billion per-year. In addition, economic analysts at the Phoenix Center estimate that the indirect benefits from a full-fledged public safety network could come to another $2 billion to $6 billion per-year.[34] In short, therefore, the proposal would create nearly

[33]The White House, Office of the Press Secretary (2011).; Cisco (2009).
[34] Ford and Spiwak (2011).

100,000 jobs; and over time, the network itself should generate savings or benefits of some $4 billion to $8 billion per-year.

The network's main purpose is to support the daily operations of police, fire fighters and other public safety agencies – for example, by providing real-time video surveillance of critical areas and crime and fire scenes, so police and firefighters can monitor and deploy the appropriate personnel, hour-to-hour. In addition, the ICT-based network would provide wireless data and communication networks for officers in the field to consult databases, building plans and schematics, and public and private surveillance systems. Further, first-responders on their way to fires, hostage situations, and other incidents will be able to review real-time video from the incident scenes, as well as public and private databases, to better plan and coordinate their responses. The President's proposal also includes other provisions that could further expand its economic benefits.[35] For example, other public agencies could be permitted to use the network. The plan also would encourage police and firefighting agencies to enter into partnerships with appropriate commercial operators, so each side could leverage the experience and assets of the other. Finally, the network's value also could rise sharply when major terrorism and natural disasters strike. In fact, the original impetus for the proposal came from the 9/11 Commission's criticism of the lack of inter-operable communications systems among the diverse first-responders at the World Trade Center and the resulting vulnerabilities for homeland security.[36]

The proposal to allocate nearly $11 billion to create a wireless local, regional and national data and communications network for public safety officials and agencies represents an acute public policy application of ICT that should generate large economic benefits. The initial appropriation should generate nearly 100,000 jobs; once in place, the system should produce an estimated $2 billion per-year in efficiency savings by police and fire departments, as well as another $2 billion to $6 billion per-year benefits from additional lives and property preserved from the application of ICT to the daily operations of public safety officers. And these benefits could be much greater if they are applied, as they almost certainly would be, to instances of major terrorism or large natural disasters.

Investments in a Smart Grid

Another current example of ICT-related funding by the federal government that will produce significant economic benefits is the provision in the American Recovery and Reinvestment Act of 2009 allocating $3.4 billion for investments in a "Smart Grid," the largest energy-grid modernization effort on record. A Smart Grid is an ICT-based network that delivers electricity to businesses and consumers using two-way digital data and communications systems, often linked directly to systems and appliances in offices, factories and homes. To achieve this, the Smart Grid overlays the existing electrical grid with a range of information and communications technologies, including extensive deployment of smart meters. As with the federal support for a wireless broadband public safety data and communications network, the Smart Grid would generate significant direct and indirect savings and economic benefits.

[35] Testimony of Paul Steinberg (2011)
[36] Moore (2010).

The most direct benefit from the appropriation is the jobs it has created: Based on ICT industry's allocation of expenditures between labor and capital investments, and average salaries in the sector, the provision has directly generated about 24,000 jobs, plus perhaps another 5,000 jobs associated with the program's capital purchases. Moreover, this represents an initial investment in the long-term creation of an ICT-based Smart Grid, over some 20 years, that will probably be funded by both the private utility industry and government. The creation of a nationwide Smart Grid will entail hundreds of thousands of additional jobs, including smart-meter manufacturing workers; engineering technicians, electricians and equipment installers, IT system designers and cyber security specialists, data entry clerks and database administrators, and business and power system analysts.[37] The greatest economic benefits, however, will follow from the actual use of the Smart Grid. For example, in a recent analysis, the Electric Power Research Institute (2010) identified additional new capacities possible with a Smart Grid.[38] They include reconfigurations so utilities can prevent "fault currents" from exceeding damaging levels, wide-area monitoring of the condition of the bulk power system in real time, real-time determination of the capacity to carry load for each element in the grid, and advanced metering systems for real time management of power demand by customers based on adjusted pricing.

Another often-cited benefit of an ICT-based Smart Grid is fewer power outages. If the Smart Grid can reduce those outages by 20 percent, as predicted by the National Energy Technology Laboratory,[39] it would save $20 billion per-year from some $100 billion in current annual costs from such outages as estimated by the Electric Power Research Institute (EPRI).[40] Industry experts have enumerated additional applications of a Smart Grid that also would generate significant savings or economic benefits,[41] including automating the operations of the core grid, collecting the data required to reduce the cost and increase the effectiveness of maintenance programs, smart metering to shift power use by businesses and households from high-use times of the day and month to lower-use days and times, and the eventual development and operations of "smart buildings" that automatically optimize their use of electricity.

Some of these applications are possible today. For example, Oberlin College conducted a competition a half-decade ago in which it challenged its students to conserve and shift their electricity consumption.[42] On average, dormitories were able to cut their electricity use by 32 percent; but two dormitories that received real-time feedback on their energy use and costs, through smart metering within a wireless data communication network tied to the electricity grid, reduced their electricity consumption by 56 percent. A Smart Grid also could support homeowners and businesses that want to produce their own energy, using small-scale generation from photovoltaics, solar thermal energy, and oil and natural gas-fired generators. The ICT-based grid could not only accommodate the use of such "microgeneration" and provide outside energy when needed; it also could transfer excess energy from microgenerators to other customers and credit the small producer. Similarly, with the deployment of a Smart Grid, drivers

[42] Dormitory Energy Competition at Oberlin College (2005).

of hybrids or all-electric cars could create and store electricity in their automobiles and then sell it back to the grid whenever they chose to do so.

Beyond the 29,000 jobs created directly by the appropriation and potential $20 billion in annual benefits or savings from reducing power outages, the National Energy Technology Laboratory (2010), has identified other potential economic benefits of a Smart Grid.[43] For example, the ICT components of a Smart Grid would monitor the energy flows to large customers and reduce the incidence of poor power quality, generating benefits estimated at $10 billion per-year. Raising the stakes on quality control, the Smart Grid also could virtually eliminate the danger from large-scale blackouts, which cost the economy some $10 billion each.

Furthermore, by improving the efficiency of the energy infrastructure, from generation to consumer, and of local and national electricity markets, the Smart Grid will reduce electricity consumption and drive down prices, relative to the continued reliance on less efficient energy infrastructure. Recent experiments suggest that these savings could cut current electricity bills by 10 percent to 15 percent: In 2010, American households and businesses spent $370.5 billion for electricity, suggesting economic benefits from this source of $37 billion to $55 billion per-year.[44] The ICT-enabled monitoring of the power grid also should reduce transmission and delivery losses (T&D) by at least 10 percent, producing another $2.5 billion in annual benefits;[45] and cutting the costs of transmission congestion costs by 10 percent, a reasonable target, would save another $2 billion per-year. The system's continuous ICT-based monitoring also should reduce operations and maintenance costs by at least 10 percent, generating another $4 billion in annual savings. These efficiency gains should not reduce overall employment: While some of the savings in operations and maintenance may cost jobs, the efficiency gains generate new demand for other and services, leading to more employment to produce, distribute and sell them. Finally, the deployment of a Smart Grid would allow utilities to eliminate or defer a share of the planned, large capital investments – in centralized generating plants, substations and transmission and distribution lines – reducing costs by an average of roughly $2 billion to $6 billion per-year.[46]

All told, these enumerated benefits from the application of ICT to the nation's electricity grid come to some $70 billion to $90 billion per-year. This estimate is reasonably close to an analysis by the Electric Power Research Institute working with the Department of Energy: Their study projects total Smart Grid costs of $340 billion to $480 billion over 20 years, and economic benefits of $1.3 trillion to $2 trillion over the same period.[47] That suggests benefits that would average $65 billion to $100 billion per-year, and exceed costs by roughly 3-to-1 to 5-to-1. That would mean net benefits averaging $48 billion to $76 billion per-year. With regard to jobs, a report by the energy consultancy KEMA (2008) has forecast that building and operating a Smart Grid would create thousands of jobs across the country, including smart meter manufacturing workers; engineering technicians, electricians and equipment installers, IT system designers and cyber security specialists, data entry clerks and database administrators, and business and power

system analysts.[48] To be sure, these benefits will be accrued over many years. Smart Grid activity in the United States is focused today on "advanced metering," a precursor to a genuine Smart Grid. Duke Energy is the only utility that has filed plans with regulators for elements of a Smart Grid, although others have filed plans that involve advanced metering. These activities, however, were spurred in part by the 2009 funding, which may be seen years from now as the seed money for an ICT-based transformation of our energy infrastructure.

Reducing the Corporate Tax Burden

The tax treatments of corporate investments, their financing and their returns affect the cost of capital for businesses and thus actual investment levels, including the investments in ICT that drive the direct and spillover benefits documented earlier in this study. Many economists have studied the impact of the corporate tax burden and its top tax rate on investment, here and in other nations. This research shows, first, that capital investment responds to both the marginal corporate tax rate and the "effective" tax rate or tax burden, which takes into account deductions and credits for particular investments and expenditures. It is also often noted that over the last decade, the United States has maintained a relatively high marginal tax rate and tax burden on corporate profits, while most European countries have reduced their corporate taxes.[49] This research suggests that our high corporate tax rates and tax burdens may contribute to our relatively low domestic investment rates.

The high U.S. corporate tax burden and rates may particularly affect investment by ICT industries, because the value of corporate tax preferences critical to investment is less for the ICT sector than for many other industries. In addition, as noted by the Joint Committee on Taxation (JCT), the ICT industry has not received new tax benefits since at least 1986.[50] By contrast, in 2004 alone, Congress provided new tax preferences for railroads, film and TV production, and biodiesel blender makers; and the 2009 stimulus included new tax expenditures for a range of clean energy producers and consumers.

Unsurprisingly, there has been considerable research and debate recently about the economic impact of reducing the corporate tax burden and marginal tax rate. We leave that debate to others. Instead, we focus on how a 10 percent reduction in the corporate tax burden or effective rate would affect investments by ICT companies and ICT investments by other industries, because those investments produce disproportionately large benefits for GDP, productivity and wages. As we will see, such a 10 percent tax reduction would increase investments in ICT by nearly $71 billion over several years, which in turn would raise productivity and total spending on compensation by nearly $450 billion. Over several years, those investment and productivity gains would drive higher levels for compensation, sufficient to cover wage increases averaging $5,424 per-worker across the economy, or some 6.8 million new jobs, or some combination of higher wages and additional jobs.

[48] KEMA (2009).
[49] A recent study from the American Enterprise Institute, for example, found that among all OECD nations, the United States has the second highest effective corporate tax rate and combined national and local marginal corporate tax rate (Japan is number one in both cases)Hassett and Mathur (2011).
[50] Joint Committee on Taxation (2011).

To calculate these effects, we begin by estimating how much investment would increase in response to a reduction in its tax burden, or in economic terms, "the elasticity of investment with respect to effective corporate tax rates." A recent review of the international tax literature found that this average elasticity is 0.6: A one percent reduction in the corporate tax burden is followed on average by a 0.6 percent increase in investment.[51] Other studies have found larger responses, as high as 3.3 percent,[52] but here we adopt the more conservative value.

Applying this value, we estimate how much each industry would expand its investments, in ICT and overall, over three-to-five years, if Congress reduced the corporate tax burden by 10 percent. (Table 5, below) Over several years, American businesses would increase their ICT capital stock by some $71 billion, relative to what we would expect under the present corporate tax. The largest increases in ICT investments would occur in the information industry; manufacturing; professional, scientific and technical services; and transportation and warehousing. American businesses would increase their overall capital investments by $990 billion, with the largest increases occurring in manufacturing and utilities, mining and oil and gas exploration, finance and insurance, and real estate, rentals and leasing.

Table 5: Impact of a 10 Percent Reduction in Corporate Tax Burden On ICT Investment and Total Capital Investment, by Industry ($ millions)

Industry	ICT Capital Stock (millions)	Total Capital Stock (millions)	Increase in ICT Capital Stock (millions)	Increase in Total Capital Stock (millions)
Ag., Forestry, Fishing	$2,397	$492,462	$144	$29,548
Mining, Oil, Gas Exploration	$13,751	$1,269,032	$825	$76,142
Utilities	$23,575	$1,823,966	$1,415	$109,438
Construction	$28,462	$283,702	$1,708	$17,022
Manufacturing	$150,873	$2,309,681	$9,052	$138,581
Wholesale Trade	$61,282	$502,948	$3,677	$30,177
Retail Trade	$29,057	$1,036,955	$1,743	$62,217
Transportation & Warehousing	$109,863	$1,105,476	$6,592	$66,329
Information	$270,001	$1,162,888	$16,200	$69,773
Finance & Insurance	$114,331	$1,278,624	$6,860	$76,717
Real Estate, Rental, Leasing	$55,510	$1,320,507	$3,331	$79,230
Profess'al, Scientific & Tech. Services	$153,348	$371,962	$9,201	$22,318
Mgt of Companies	$59,743	$479,134	$3,585	$28,748
Admin., Support & Waste Mgt.	$32,639	$226,256	$1,958	$13,575
Education	$9,418	$429,122	$565	$25,747
Health Care, Social Assist.	$43,835	$1,187,396	$2,630	$71,244
Arts, Entertain., Recreation	$4,250	$226,104	$255	$13,566
Accommodation, Food Services	$8,587	$524,951	$515	$31,497
Other Services	$8,908	$464,058	$534	$27,843
Total	**$1,179,830**	**$16,495,224**	**$70,790**	**$989,712**

Next, we look at how these increases in ICT investments would affect each industry's wages and employment. For this analysis, we use BEA data on compensation and ICT

[51] Gordon and Hines (2002).
[52] De Mooij and Ederveen (2003).

investment for 1998 to 2007, and calculate how much compensation rises when an industry increases its ICT investments – the "elasticity of compensation to ICT investment." This analysis of total compensation covers both increases in wages and increases in the numbers of workers earning them. We cannot know how much of the gains from ICT investments would go to wages and how much to additional jobs, although we would expect that more would go to higher wages then additional jobs, because ICT investment is associated closely with gains in productivity that lead to higher wages. Table 6, below, shows the increases in total compensation spending, by industry, that should follow from the higher ICT investments expected from a 10 percent reduction in corporate tax burdens.[53]

The analysis shows that these increases in ICT investments would lead to increases in compensation spending ranging from 3 percent (accommodations and food services; utilities; management of companies and enterprises; and mining, oil and gas exploration) to 16 percent (transportation and warehousing; information; and real estate, rentals and leasing). Compensation spending would increase by $35.5 billion in manufacturing, by $39 billion in health care and social assistance, by over $40 billion in the information sector, and by nearly $79 billion in finance and insurance. All told, the increases in ICT capital investments would raise private-sector compensation spending by nearly $450 billion or by an average of 7 percent.

Table 6. Impact of Increased ICT Capital on Total Compensation, By Industry, Over Time ($ billions)

Industry	ICT Capital After Tax Cut	Current Industry Compensation Spending	Post-tax Compensation Spending	Increase in Compensation Spending
Ag., Forestry, Fishing	$2.54	$43.77	$46.86	$3.10
Mining, Oil, Gas Exploration	$14.58	$64.77	$66.80	$2.03
Utilities	$24.99	$67.04	$69.01	$1.97
Construction	$30.17	$378.35	$395.94	$17.60
Manufacturing	$159.93	$858.65	$893.15	$34.51
Wholesale Trade	$64.96	$410.86	$452.46	$41.60
Retail Trade	$30.80	$480.42	$515.81	$35.39
Transportation & Warehousing	$116.46	$245.93	$284.60	$38.66
Information	$286.20	$248.36	$288.75	$40.39
Finance & Insurance	$121.19	$568.12	$646.80	$78.68
Real Estate, Rental, Leasing	$58.84	$102.47	$118.97	$15.51
Prof'al, Scientific, Tech. Services	$162.55	$669.14	$696.35	$27.21
Mgt of Companies	$63.33	$212.83	$219.45	$6.62
Admin. Support & Waste Mgt.	$34.60	$286.52	$305.67	$19.15
Education	$9.98	$135.62	$146.29	$10.67
Health Care, Social Assist.	$46.47	$855.87	$894.91	$39.05
Arts, Entertainment, Recreation	$4.51	$322.86	$337.66	$14.79
Accommodation, Food Services	$9.10	$242.64	$250.10	$7.46
Other Services	$9.44	$234,747	$247.26	$12.51
Total	**$1,250.62**	**$6,428.95**	**$6,876.84**	**$447.89**

[53] These estimates are based on the elasticity of an industry's ICT investments to the reduction in its effective tax rate, and the elasticity of an industry's compensation costs to increases in its stock of ICT.

Since we cannot know how this additional compensation spending would be divided between higher wages and additional jobs, we provide the two upper bounds: The increase in per-worker wages or compensation if all of the additional resources went to that use with no increase in the number of workers; and the increase in jobs if all of those resources went to job creation with no increase in wages. (Table 7, below) The reality would fall somewhere in-between. For example, the additional investment in ICT by manufacturing firms would lead to some combination of wage increases of up to $2,993 per-worker and job gains of up to 463,347 slots, a midpoint of about $1,500 in higher wages per-worker and about 232,000 additional jobs in manufacturing. Similarly, the construction industry would see some combination of wage increases of up to $2,957 per-worker and job gains of up to 276,768 positions. Across the economy, the rule would be, the greater the gains in wages, the smaller the increase in jobs (and vice versa).

Table 7. Impact of Increased ICT Capital on Wages and Employment, By Industry

Industry	Average Compensation Per-Worker, 2009	Post-Tax-Cut Increase in Compensation Per Worker, Upper Bound	Total Employment, 2009	Post-Tax-Cut Increase In Employment, Upper Bound
Ag., Forestry, Fishing	$41,366	$2,926	1,058,000	74,843
Mining, Oil, Gas Exploration	$102,648	$3,220	631,000	19,796
Utilities	$120,795	$3,549	555,000	16,306
Construction	$63,578	$2,957	5,951,000	276,768
Manufacturing	$74,477	$2,993	11,529,000	463,347
Wholesale Trade	$75,888	$7,684	5,414,000	548,223
Retail Trade	$37,807	$2,785	12,707,000	936,057
Transportation & Warehousing	$61,376	$9,649	4,007,000	629,936
Information	$94,182	$15,316	2,637,000	428,830
Finance & Insurance	$102,051	$14,133	5,567,000	770,963
Real Estate, Rental, Leasing	$54,824	$8,831	1,869,000	301,061
Prof'al, Scientific, Tech. Services	$93,221	$3,791	7,178,000	291,925
Mgt of Companies	$118,437	$3,681	1,797,000	55,855
Admin. Support & Waste Mgt.	$43,158	$2,884	6,639,000	443,607
Education	$48,315	$3,801	2,807,000	220,804
Health Care, Social Assist.	$58,373	$2,663	14,662,000	668,892
Arts, Entertainment, Recreation	$200,661	$9,195	1,609,000	73,728
Accommodation, Food Services	$27,162	$836	8,933,000	274,784
Other Services	$40,600	$2,164	5,782,000	308,148
Average or Total	**$76,785**	**$5,424**	**101,332,000**	**6,803,873**

If all of the additional resources for compensation spending went into higher wages with no additional jobs, the higher ICT investments would raise the wages of an average U.S. worker by $5,424 over several years, ranging from a high of $15,316 per-worker in the information industry and $14,133 in finance and insurance, to a low of $836 per-worker in the accommodations and food service sector and $2,164 in other services. Alternatively, if all of the new ICT-driven spending for compensation went into job creation with no increase in wages, it would mean an additional 6.8 million new jobs over several years. The largest job gains would occur in retail trade (936,057 positions), finance and insurance (770,963 jobs), health care and social assistance (668,892 jobs), and transportation and warehousing (629,936 positions).

Finally, the increases in compensation correspond economically to the increase in value-added or GDP. Therefore, the additional investments in ICT spurred by the reduction in the corporate tax burden would produce spillovers that would increase the value-added produced across the economy by $447.9 billion.[54]

VI. Conclusion

Information and communications technologies have played a unique role in the development and success of the American economy over the last two decades. ICT industries have grown more rapidly than any other economic sector, and the average compensation of ICT industry workers now runs more than 80 percent more than the average for all other U.S. industries. Moreover, ICT has been on the cutting edge of economic innovation. These innovations have diffused across nearly every other industry, increasing efficiency and driving additional innovations in the way other industries operate and the goods and services they produce.

This study has measured these various effects. We found that in 2009, ICT itself was responsible for some $600 billion in value-added, or 4.2 percent of GDP. We further found that the ICT investments by other industries were responsible for an additional $400 billion in value-added produced by those industries. In short, ICT generates unusually large and extensive "spillover benefits" for other industries and their workers. All told, ICT industries in 2009 were responsible, directly or indirectly, for the production of about $1 trillion in goods and services, or 7.1 percent of GDP in that year. Given ICT's disproportionate impact on U.S. growth, public policies that promote investments in ICT also would produce disproportionate benefits for the economy.

These economic benefits also are apparent in our analysis of the impact of three ICT related public policies. A proposed $10.7 billion public investment in an ICT-based wireless data and communications network for police and other public safety agencies would lead to the creation of nearly 100,000 new jobs in ICT industries alone and, over time, spillover benefits of some $4 billion to $8 billion per-year. The $3.4 billion stimulus funding for an ICT-based wireless data and communications network for a "Smart Grid" should directly produce nearly 30,000 new jobs and, if this funding becomes seed money for the full development of an ICT-based Smart Grid, the net benefits will range from $48 billion to $76 billion per-year. Finally, a 10 percent reduction in corporate tax burdens would spur nearly $71 billion in additional investments in ICT goods and services by other industries. And after several years, those increases in ICT capital would produce an additional $448 billion in annual GDP and significant increases in compensation and/or employment in every industry. If all of these benefits went to higher wages with no additional jobs, it would over time raise the average compensation of American workers by $5,424; and if all of the benefits of the additional ICT investments went to job creation, it would over time generate more than 6.8 million additional jobs.

[54] This is derived from Table 6, the differences between total current compensation and total compensation after the tax change and additional ICT investments.

The critical role of ICT in the current growth and development of the U.S. economy is also central to establishing and maintaining a comparative advantage for American companies and workers in the global economy. ICT advances and their adoption by industries across the U.S. economy help drive innovation in every sector. With scores of developing nations now able to operate standard technologies and business methods at less cost than in the United States, the American capacity to apply ICT to develop and adapt new innovations for every phase of the economic process has become critical to U.S. competitiveness in a global economy.

Appendix

Table A-1. Contribution of ICT to the Output on Industries, By Industry, 2009

Industry	Contribution of ICT (millions)	ICT Contribution to Industry Output
Farms	$731	0.24%
Forestry, fishing, and related activities	$117	0.28%
Oil and gas extraction	$595	0.32%
Mining, except oil and gas	$540	0.71%
Support activities for mining	$662	0.75%
Utilities	$1,733	0.44%
Construction	$13,809	1.27%
Wood products	$1,174	1.48%
Nonmetallic mineral products	$1,573	1.70%
Primary metals	$3,598	2.00%
Fabricated metal products	$6,983	2.30%
Machinery	$6,683	2.55%
Computer and electronic products	$55,310	15.66%
Electrical equipment, appliances, and components	$3,348	3.23%
Motor vehicles, bodies and trailers, and parts	$10,713	3.07%
Other transportation equipment	$26,258	10.52%
Furniture and related products	$1,276	2.09%
Miscellaneous manufacturing	$2,848	1.93%
Food and beverage and tobacco products	$4,746	0.62%
Textile mills and textile product mills	$567	1.24%
Apparel and leather and allied products	$99	0.55%
Paper products	$2,439	1.54%
Printing and related support activities	$2,270	2.53%
Petroleum and coal products	$523	0.11%
Chemical products	$7,643	1.24%
Plastics and rubber products	$3,064	1.80%
Wholesale trade	$10,591	1.04%
Retail trade	$14,363	1.20%
Air transportation	$214	0.16%

Executive Summary

The public safety community is about to embark on the most important upgrade to its mission-critical communications systems ever. Today, police, sheriff, fire, and EMS personnel only have access to voice communications on dedicated public safety spectrum. However, since the Federal Government allocated this spectrum for public safety use over the course of many years, it is not contiguous in nature but available on six different portions of the wireless spectrum.

The voice channels on each of these portions of the spectrum allocated to public safety communications voice are not sufficient to provide communications for all of the agencies and, therefore, over the years, some agencies make use of one portion of the spectrum while other agencies are assigned channels on another portion of the spectrum. This has resulted in a lack of interoperability between agencies, even within the same jurisdiction. It is not unusual for the police department in a city to be on a different portion of the spectrum than the fire and EMS departments. The result of this is that when these agencies are working side-by-side on an incident they cannot directly communicate with each other.

In addition, since these channels are suitable for voice communications only, the public safety community has little or no access to data services, pictures, or video. In order to partially solve some of these problems, some departments have entered into service agreements with commercial wireless operators for wireless phone, messaging, and broadband services. However, during major incidents these commercial networks are jammed with news media and citizens trying to contact their offices or loved ones. At the time this capability is needed most by the first responder community, it becomes unavailable due to commercial network overload.

The lack of interoperability that has been an issue for public safety nationwide for more than three decades was brought to the nation's attention during the terrorist attacks on 9/11 and again during Katrina. A number of different agencies all responded to provide services and were unable to coordinate with each other due to a lack of interoperable voice communications along with the lack of data and video communications. Since these incidents, many agencies have upgraded their voice communications systems and banded together to form regional and even statewide voice communications systems. However, because of the nature of their spectrum allocations they have not been able to address the issue of providing broadband communications services to those in the field.

Recently, Congress and the FCC allocated additional spectrum for public safety in what is known as the 700-MHz band. This band was occupied by TV stations above channel 53 that were relocated lower in the TV spectrum. The resulting band was divided into blocks. Public safety received two blocks of this spectrum: one for additional voice channels and one for a nationwide, fully interoperable broadband system that will add data, picture, and video capabilities for first responders. AT&T, Verizon, and others were then permitted to bid on other blocks within this band. The block adjacent to the public safety allocation known as the D Block was supposed to have been sold at auction with the condition that the winner would work with public safety to build out a nationwide private/public partnership system that would result in a shared network for both the private network operator and for public safety.

For a number of reasons, no bids were received for this spectrum, thus it was not auctioned. Today it sits idle. The public safety community quickly rallied and joined forces in order to convince both the FCC and Congress that the D Block should be reallocated to public safety so the amount of broadband spectrum available meets the needs of the public safety community on a daily basis. During the past two years, public safety has gained a lot of traction for this reallocation of the D Block but has also faced some stiff opposition from those who would like to see it re-auctioned for commercial purposes. Most of the discussions about who should gain access to the D Block have to do with how much broadband spectrum public safety really needs on a daily basis for local incidents. There have been many studies (all theoretical in nature) about the capacity of the existing public safety spectrum but until now there have been no real-world tests to validate whether the Public Safety Spectrum Trust (PSST) spectrum is really sufficient for public safety's daily requirements.

While this debate continues, the FCC issued waivers to 21 jurisdictions allowing them to start building their portion of the network. The San Francisco Bay Area applied for and received one of the waivers. The East Bay Regional Communications System Authority in partnership with the Bay Area Urban Area Security Initiative (UASI) developed Project Cornerstone as a proof of concept for the larger LTE network planned for the Bay Area. For the first time, we were able to conduct real-world testing of the first demonstration system of public safety broadband. The methodology and the test results are presented in the following report.

The conclusion reached by Andrew Seybold, Inc. as a result of this in-depth testing is that the presently allocated 10 MHz of spectrum (5 MHz by 5 MHz) for public safety's exclusive use is not sufficient to meet its needs on a daily basis. One of the prime advantages to implementing a nationwide broadband network is to enable first responders in the field to have access to video for the first time. Think of this as giving sight to the blind. For the first time, those responding to incidents will be able to see video from a fixed camera near the incident. For the first time, those in the command center in charge of an incident will be able to view, in real time, video sent back from the scene. The SWAT commander will be able to see exactly what his team's sharpshooters can see using their rifle scopes, and during a bomb incident, live video of the bomb can be made available to bomb experts anywhere in the world, one of whom might recognize it and be able to guide those at the scene as to the best way to disarm it and render it harmless.

In order to accomplish all of this and more, including having access to information regarding an incident, the history of the perpetrator, or perhaps still pictures of a suspect wanted for a crime, public safety needs sufficient bandwidth for this nationwide broadband system and as our test results conclusively show, the 10 MHz of spectrum presently allocated to public safety does not provide sufficient bandwidth for incidents that occur in cities and counties on a daily basis. Therefore, the 700-MHz spectrum known as the D Block needs to be reallocated to public safety to ensure it has the bandwidth it needs.

Introduction

Andrew Seybold, Inc. (ASI) was contracted by the East Bay Regional Communications System Authority (EBRCSA) to undertake a series of network capacity tests for the first 700-MHz system in the United States to deploy LTE. This network operates in 10 MHz (5 MHz by 5 MHz) of spectrum licensed to the Public Safety Spectrum Trust (PSST) and under a waiver granted to EBRCSA by the FCC.

EBRCSA, in turn, will be integrated with the planned nationwide fully interoperable broadband network dedicated to public safety and providing, for the first time, a nationwide public safety network based on commercial standards that will enable the first responder community to move equipment and manpower anywhere in the nation and be able to communicate with all of the other agencies involved in a major incident. The lack of interoperability for public safety agencies has created problems during major incidents for more than thirty years but was brought to the attention of the public during the Oklahoma City bombing, the 9/11 tragedy, and major hurricanes such as Katrina.

The reason for the engagement of ASI to perform capacity tests on this system was many fold: First, it is important for network planning purposes to understand both the capacity and the limitations of the network. Next, there are ongoing discussions about the amount of spectrum, and therefore the amount of capacity the public safety community needs on a daily basis. The public safety community and its supporters believe that 10 MHz of broadband spectrum is not sufficient for the types of broadband services that will be required on a daily basis, especially in major metropolitan areas. There are also those who believe that the D Block, the additional 10 MHz of spectrum being requested, should instead be auctioned for use by a commercial network operator.

Up to this point, all of the capacity models that have been run by those involved with the public safety community have indicated that 10 MHz of spectrum is not sufficient for normal daily data and video requirements while those who are in favor of auctioning the D Block have presented their own capacity models that are designed to support their own position. These tests conducted on the Cornerstone system are the first real-world tests conducted on a live system, and simulating a variety of incidents that are commonplace and handled, on a daily basis, by police, fire and EMS agencies either acting alone or in combination with the other agencies.

ASI has been involved in these discussions and Andrew M. Seybold has filed numerous comments with the FCC based on our own computer-generated capacity studies. We found what we believe to be a major discrepancy in the way capacity was measured in the case of those who are proponents of the D Block auction. The capacity calculations used by these companies and the FCC were based on capacity models developed by the 3GPP and were based on a grid of 19 cells sites, each with 3 sectors, for a total of 57 cell sectors. Interference was assumed to be equal across all of these cell sectors and the capacity measurements were based on spreading a user base across all of the sectors. While this capacity modeling method may in fact work for commercial network deployments, it is not germane when running capacity studies for a public safety broadband system.

The public safety community—police, fire, and EMS—responds to multiple incidents per day within their own jurisdictions that involve multiple public safety responders. These incidents, for the most part, are confined to a small geographic area that will usually be provided coverage by only one or at the most two cell sectors of the LTE broadband network. Therefore, the most important measure of capacity for a public safety broadband system needs to be focused on the capacity within a single cell sector rather than over a broader area. The testing methodology developed by ASI was based on self-contained incidents confined to a small geographic area and modeled based on real-world incidents that the public safety community responds to every day.

As an incident grows in complexity the number of first responders on the scene increases rapidly and the amount of video and data resources needed to manage the incident will increase exponentially. Incidents can grow in size and complexity quickly. During the early stages, while there is an incident commander on the scene, the demands that will be placed on the broadband network will continue to expand. If the incident needs to be managed for a longer period of time, additional resources such as command-and-control vehicles and incident management personnel will be put into place. At this point, it will be possible to manage the demand for voice, data, and video services, but in the early stages of an incident, those who are responding are occupied with sizing up the incident, deploying personnel, ensuring that the general public is out of harm’s way, and coordinating resources that are either on the scene or responding to it.

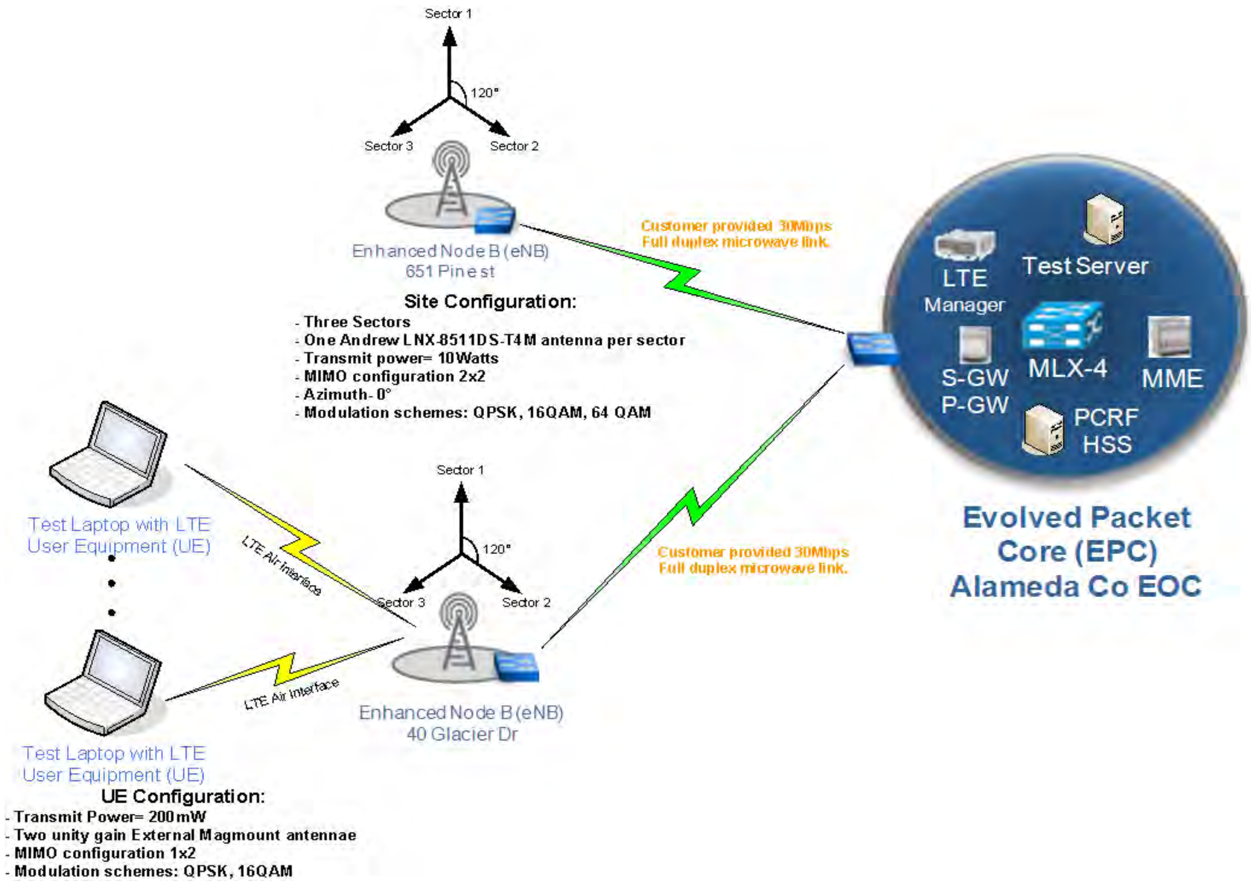
As an incident builds, so too will the demand placed on the LTE broadband network, and since the vast majority of these incidents will occur within a small geographic area, the coverage of that area will, in most cases, be provided by a single cell sector or two overlapping cell sectors. Further, it is important to understand that a blocked call or lack of available bandwidth during the incident as it grows in size and complexity is not an option for public safety. Therefore, the total amount of bandwidth available within a single cell sector is of paramount importance when designing the public safety broadband network and the amount of capacity available within each cell sector is directly proportional to the amount of bandwidth available within the cell sector. It is imperative that there be enough bandwidth available to handle the increased demand in service on a daily basis.

Based on our testing and the resources public safety agencies have identified as required for these types of incidents, ASI has concluded that 10 MHz of broadband spectrum (5 MHz X 5 MHz) is not sufficient to meet the needs of the public safety community on a daily basis in metropolitan and suburban areas of the United States.

The Network Under Test

The LTE network under test is located in Alameda County, California. The Evolved Packet Core (EPC) that is used to manage the network, identify units on the network, and for all command-and-control functions is located in the Alameda County Emergency Operations Center (EOC). The EPC is connected to the two cell sites via County Microwave with a total per cell site capacity of 30 Mbits per second. For the purposes of these tests, the test server was co-located at the Core in order to ensure that there were no network bottlenecks between the test server and the network under test.

This is a diagram of the Alameda County test network:



Each of the two active cell sites is divided into three sectors, which is the standard cell site configuration for all commercial cellular networks. For the purposes of these tests, all were conducted within the coverage of a single cell sector for each of the two sites and it was verified that there was no network traffic on the other two sectors. The total backhaul of 30 Mbits per second provided by the County Microwave system was available for the single sector under test.

The field devices we used were Panasonic Toughbook computers of the same variety that are in daily use within the public safety community, and the LTE field devices were standard LTE USB modems that were connected to the Toughbooks with USB cables. These USB modems were connected to two unity gain antennas mounted on the roofs of the test vehicles, providing the best case connectivity between the user device and the network (units with internal antennas such as handheld LTE devices when available will have degraded coverage and capabilities).

Additional network details may be found in Appendix A. The network was functional and fully operational and drive tests were conducted both by Motorola and Anritsu prior to beginning the testing. Stationary tests were conducted at multiple locations, run multiple times for verification, and the results are presented later in this report.

The Test Procedures

The test methodology developed by ASI for these capacity tests are based on real-world scenarios. That is, typical incidents that require public safety response on a daily basis. The incidents were created by ASI with the assistance of public safety officials from various police, fire, and EMS departments across the nation. They are based first on the amount of manpower and the number of units needed to respond to each of the various types of incidents and then the stated requirements in terms of video and data traffic public safety officials believe would be required for each incident. The incidents were developed using the Incident Command Structure (ICS), which is almost universally used by all public safety agencies.

The resulting scenarios included:

1. Bank robbery with potential hostage situation
   a. First responders on the scene: police
   b. Additional police response
   c. Fire and EMS staged near the scene
   d. SWAT team deployment
   e. Perimeter units to seal off the incident area
2. Multi-story building fire
   a. First responders on the scene: fire
   b. Additional fire units and EMS responding
   c. Police response for street and crowd control
3. Multi-vehicle accident, multiple injuries and extensive damage to vehicles
   a. First responders on the scene: police
   b. Fire and EMS response
   c. Additional police for traffic control
   d. Tow trucks (secondary responders)

The tests were designed around each of these incidents and the number of personnel from each agency was vetted by several departments across the country. The data and video requirements for each incident were calculated to provide uplink video to the dispatch center from the first unit on scene. This would then be retransmitted down to additional incoming resources including the ranking officer who responds to take command of the scene.

A video was recorded in the test area, streaming at a resolution and data rate comparable to those used in police patrol cars. Streaming software and measurement software were loaded onto both the server computer and each of the client computers. Scripts were written to calculate actual throughput, accuracy of reception, and other factors. Video files were created for both uplink (from the scene) and downlink (to the scene and responding units) and were varied in capacity requirements based on the resolution of the video required by public safety.

Prior to and during the stationary tests, both Motorola and Anritsu personnel conducted drive tests of the cell sector coverage area to verify coverage of the cell sector in use during the tests. During the actual tests, Anritsu America personnel equipped with state-of-the-art network monitoring equipment were monitoring and recording the amount of both the uplink and downlink traffic being generated during the tests.

More details of the testing methodology and the testing software used are provided in Appendix B.

The Actual Tests

The main objective of the tests was to measure network capacity in both the uplink and downlink directions from the scene of an incident and at various distances from the center of the cell sector under test. Four locations were chosen for each cell sector under test:

1. Near the cell center (highest possible data rates) location was 0.5 miles from the cell center
2. Mid-coverage (lower average data rates) location was 1.5 miles from cell center
3. Edge of cell (lowest average data rates) location was 3.8 miles from the cell center
4. A final location at the very edge of the cell coverage, in this case 4.2 miles from the cell center
5. The terrain varied for the two cell sectors under test
    a. One cell sector was located within the City of Martinez in a semi-dense building environment, but most of the buildings while multi-story were not more than six to eight floors tall
    b. The second location was more suburban in nature on the edge of Martinez with sparse housing, large trees, and in one case in the parking lot of a large shopping center.

It should be noted that LTE broadband networks are designed to provide three different data speeds down to the devices and two different data rates from the devices up to the network. Basically, those closest to the cell site will have the fastest data speeds to and from the network, those located in the middle of the cell sector coverage will have the next fastest data speed down from the network and, depending upon their location, either of the two up-to-the-network data speeds. Those toward the edge of the cell sector will have access to the slowest outbound data speed and the slower of the two up-to-the-network data speeds.

Devices and Configurations

The devices used for field testing were USB LTE modems built and designed specifically to provide service within the public safety licensed spectrum. In most cases, during the actual tests these modems were connected via USB cables to the Panasonic Toughbooks and external unity gain antennas on magnetic mounts were placed on the roof and/or back deck of the test vehicles. Two antennas were connected to each modem.

Seven Panasonic Toughbooks with Windows XP were used for all of the testing

For several of the tests, the USB modems made use of external antennas but were located within the vehicle rather than roof-mounted. This provided us with a sample of lower performance devices as well as the optimum performance of the modems using external antennas.

One of the test modems

For the most part, the modems performed well. There were several times during the tests when the modems stopped working due to glitches within the modem and the tests were stopped and restarted multiple times to verify all of the results. However, as can be seen from the data in Appendices C and D, a few of the tests are reported using only a single test session. The test Toughbooks were placed in two or three vehicles and the vehicles were placed within 50 to 300 feet of each other, simulating a number of devices within a confined location.

One of the test vehicles – note the antennas on the roof

The actual testing started with a single video or data stream from the vehicle up to the server at the Alameda County EOC, followed by a simulation of a retransmission of the video down to the scene. During each test, the number of video and/or data streams to and from the scene was increased. At the same time, Anritsu was monitoring the LTE channel in both directions and was recording the percentage of the capacity in use during each phase of the testing. This gave us a visual indication of the percentage of capacity that was being used during each phase of the testing. In addition, the other criteria measured included the quality of the video in both directions and any packet loss experienced during the up and down loading of the data files. Appendix C shows the test results as recorded for both data and video up and downloading as well as the capacity usage as measured by Anritsu during the tests. The tests were run multiple times except as noted above and the overall results are recapped in the next section of this report and in a detailed listing of the tests included in Appendices C and D.

The test results reported were collected over several multi-day test cycles, recorded on the server (uplink) and on each of the seven Panasonic Toughbooks used for testing (downlink). Anritsu's data was captured in real time. Some of this data is included in the next section and some is included in Appendix E as well. ASI is confident that these test results reflect real-world scenarios and that the results are based on best case network performance with no known chokepoints between the mobile devices and the test server located within the core of the network.

Test Results

We first measured the total capacity of the cell site by sending data from it to the mobile units (downlink or download). We measured sending data to a single mobile unit and to several mobile units at the same time. Note that when we used multiple mobile units they were all located in the same cell sector. These tests were made under what should be considered “ideal” conditions: We were the only users of the network during the tests; there was no other traffic.

As described in Appendix B, we tested at three different locations. The locations were selected to represent “best case” (near the cell tower), “typical case” (a midpoint in the cell coverage area), and “worst case” (at the cell edge) network coverage and performance. We sent random data to and from the mobile units using the same network protocols that streaming video cameras use. From these tests we arrived at the following measurements of the network’s total available bandwidth for a single sector:

Test Site	Downlink Bandwidth	Uplink Bandwidth
Glacier Street (near cell)	16 to 19 Mbits / sec	6 to 7 Mbits / sec
Sunvalley Mall (mid cell)	11 to 15 Mbits / sec	2 Mbits / sec
John Muir House (cell edge)	6 to 8 Mbits / sec	0.2 to 0.3 Mbits / sec

These measurements were made streaming data to and from a single or at most a handful of mobile units. As more mobile units are present in the cell sector, more network bandwidth will be devoted to packet management and other network traffic.

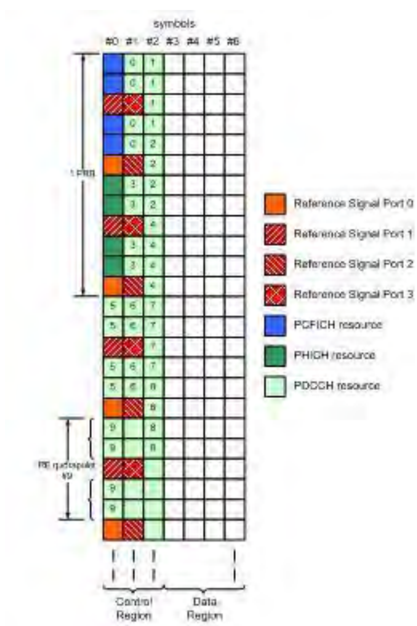


Diagram of LTE Resource Blocks

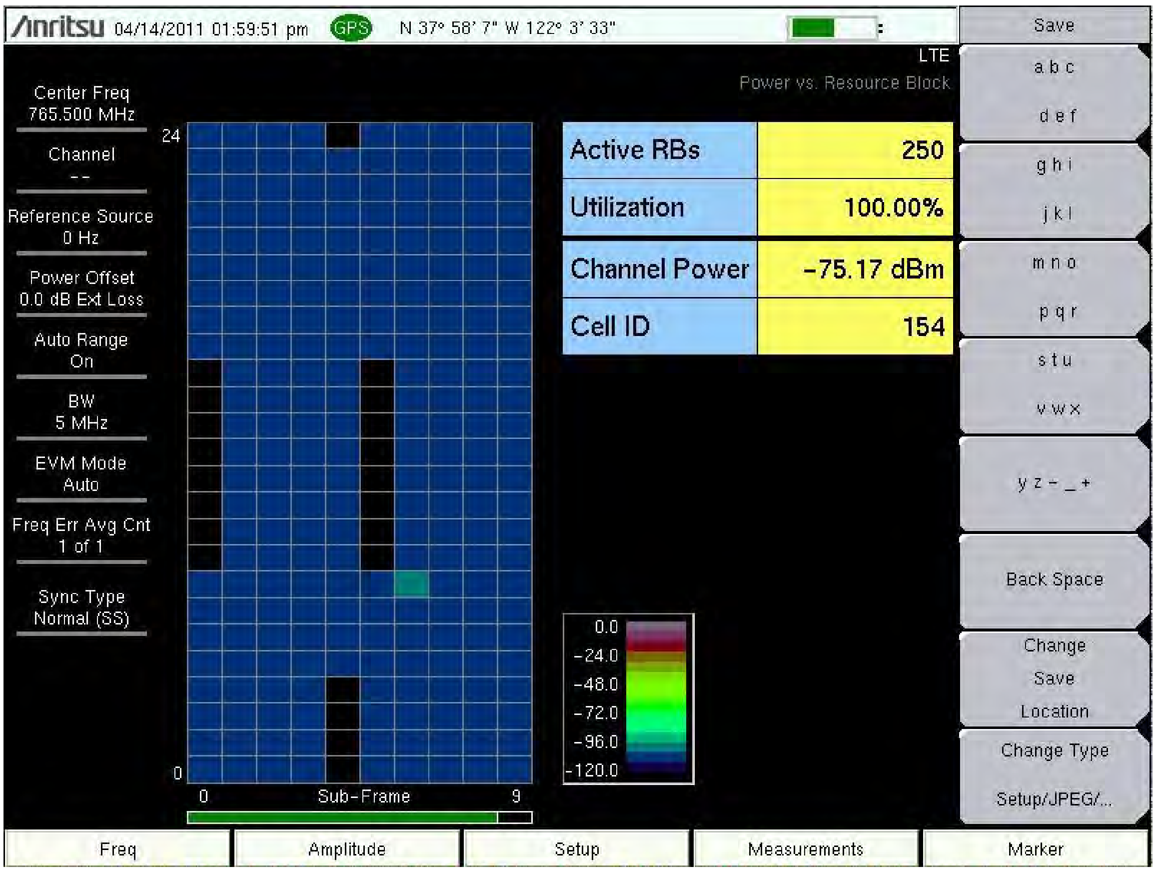
LTE assigns resource blocks to each user within a cell sector; in a 5 MHz by 5 MHz network the total number of resource blocks available is 520. Some of these blocks are reserved for signaling data (16 blocks) and network-to-device communications and are therefore not available for data communications.

The LTE carrier is made up of resource blocks. Some are reserved for signaling, but most of them are for data. Each user is assigned a number of resource blocks depending upon their priority on the system. The more data they are sending, the more resource blocks are required during their transmission. When sending a streaming video, the system allocates as many resource blocks as it can to that user.



Resource blocks in use during the network testing, courtesy of Anritsu America

Resource blocks that are not in use during these video transmissions are the signaling channel resource blocks that are used for the network and device to communicate with each other. In this particular case, 100% of the available resource blocks are being occupied with data. The signal level being reported is very good.

Besides streaming random data to and from the mobile units, we also streamed actual video using an MPEG4 codec. We recorded a VGA quality (640 x 480 pixels at about 15 frames per second) video while driving around the streets of Martinez near the test locations. This quality is typical of video cameras currently installed in police cars. The captured video enabled us to consistently stream a video with a known data rate of 1.91 Mbits per second.

At each of the test locations we simultaneously streamed videos to and from multiple mobile units while recording the received videos. Below is an image from the test video:

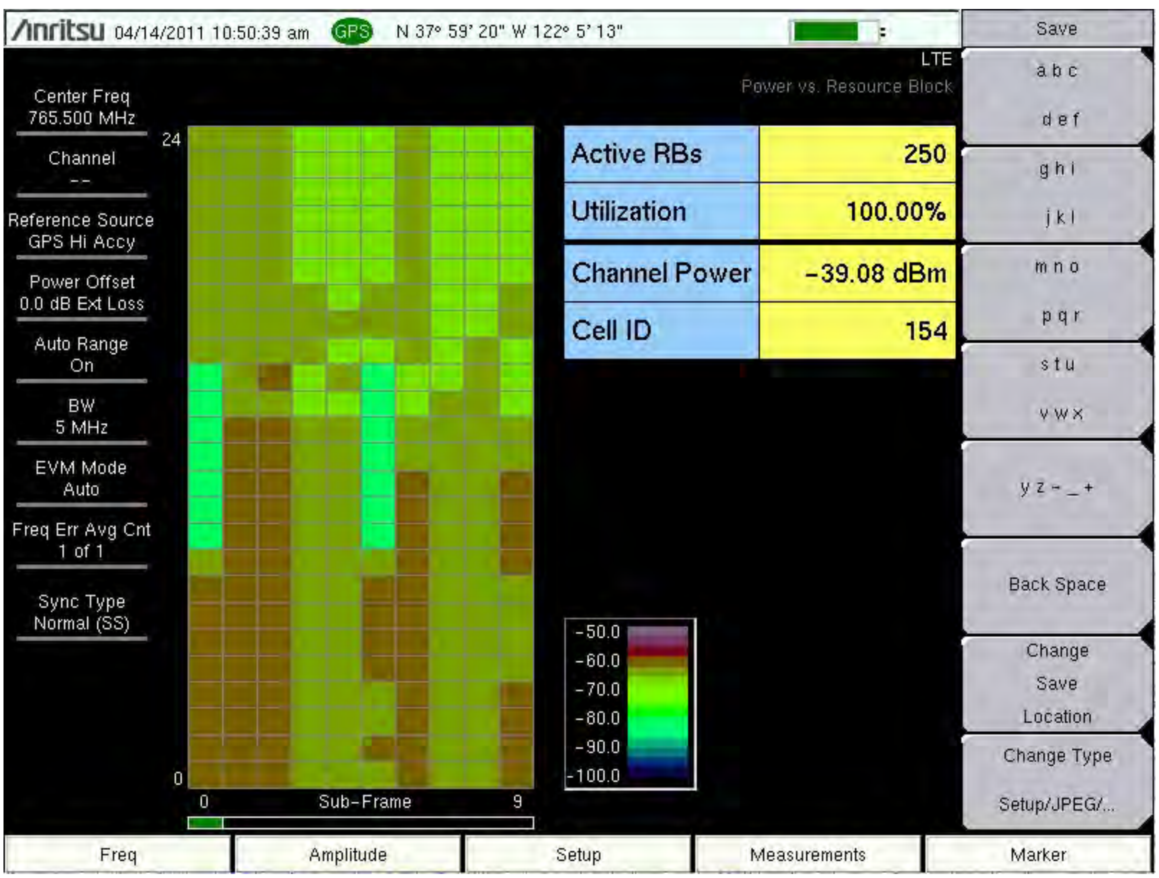
It became very obvious when there was insufficient bandwidth for a video to display, as the image quickly froze and broke up as shown below:

Actual video playbacks will be available in the PowerPoint presentation that will accompany this report and at www.andrewseybold.com.

The table below shows the number of simultaneous videos we were able to successfully stream to or from the cell site. Note that at the John Muir House location, which is at the edge of cell coverage, we were unable to stream a single video from the mobile unit to the cell site. This confirms the data measurements presented above, as we only measured an uplink bandwidth of 0.2 to 0.3 Mbits per second at that location, which is clearly below the 1.91 Mbits per second needed for the test video to successfully stream.

Test Site	Downlink Video Streams	Uplink Video Streams
Glacier Street (near cell)	5	3
Sunvalley Mall (mid cell)	3	2
John Muir House (cell edge)	2	0

More information on the data test results can be found in Appendix C. More information on the video test results can be found in Appendix D. We interpret the above numbers in the next section.



Anritsu Network Monitor showing very strong signal strength and 100% network utilization

What the Test Results Mean

Perhaps the best way to interpret the test results is to walk through two scenarios where first responders are reacting to an incident. We are not describing these incidents as they happen today, but as we project they will occur in the future when public safety LTE networks are widely deployed. The obvious change from today will be a significant increase in the use of live video feeds as a real-time information gathering tool for the first responders. The two scenarios are:

- "Barricaded Hostage": a gunman holds one or more hostages in a building
- "Suspected Bomb": a suspicious package turns out to be a bomb and must be deactivated

In each of these scenarios there will be a variety of data traffic both up to and down from the LTE network. Not every source will be active at all times. Data traffic will be transmitted from devices such as these in the field:

- Sniper scope (3.1 Mbits per second)
- Police car dashboard camera (1.9 Mbits per second)
- Helicopter-mounted camera (3.1 Mbits per second, typically via microwave link, not LTE network)
- Video feed from bomb / hazardous situation robot (3.1 Mbits per second)
- Additional handheld video feed (1.9 Mbits per second)
- Uploaded data from EMS response units (EKGs, scans, etc. at 0.1 Mbits per second)

Typically, all video feeds from the field are transmitted to the central dispatch center where the dispatcher relays one or more selected feeds to the police incident commander, the SWAT commander, and the fire chief. Therefore, in addition to the above traffic, the following data traffic will be transmitted down to devices in the field from the LTE network:

- Video feeds from any of the sources listed above, in either high resolution or converted down to a lower resolution
- Video feeds from existing wired street or highway cameras
- Video feeds from third-party cameras such as news helicopters
- Downloads of building plans, utility network plans, photographs, or other data

Beyond the above traffic related to the incident, there will be ongoing data traffic (both up and down) related to normal police activity in the same cell sector. An example of this would be a license check arising from a traffic stop.

What is important to this report is the estimated data traffic at the peak of the incident. Of course, in real life such incidents unfold over time. We are interested in projecting whether the LTE network can handle the maximum data load each scenario will generate.

Barricaded Hostage

A gunman holds one or more hostages in a building for a period of hours. The police respond with the following mobile units:

- 2 snipers
- 1 helicopter
- 1 police incident commander
- 1 SWAT commander
- 1 police car camera
- 2 police vehicles receiving video feed

At the peak of the incident, we have the following data being uploaded to the LTE network:

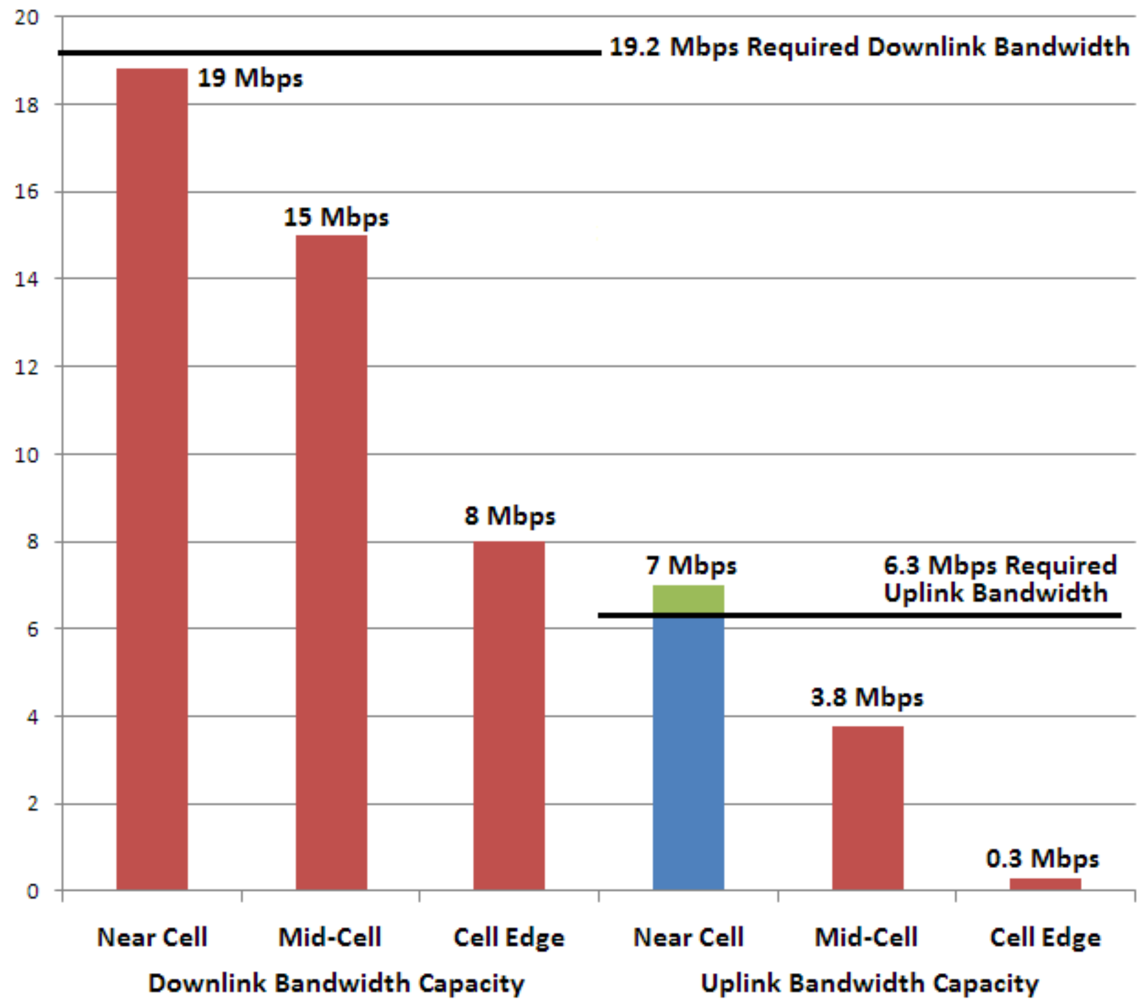
- Sniper 1 high-resolution streaming video: 3.1Mbits per second
- Sniper 2 low-resolution streaming video: 1.2 Mbits per second
- Police car camera streaming video: 1.9 Mbits per second
- “Background” ongoing police activity: 0.1 Mbits per second

This gives us a 6.3 Mbits per second uplink data stream to the LTE network and over the backhaul to the command center. We assume that the command center relays the sniper streams (one at high resolution and one at low resolution) and the helicopter stream to both the police and SWAT commanders, and the police car video stream to each of two close-in police vehicles. This means the following data are downloaded over the LTE network:

- Sniper 1 high-resolution streaming video to police commander: 3.1Mbits per second
- Sniper 1 high-resolution streaming video to SWAT commander: 3.1Mbits per second
- Sniper 2 low-resolution streaming video to police commander: 1.2Mbits per second
- Sniper 2 low-resolution streaming video to SWAT commander: 1.2Mbits per second
- Police car low-resolution streaming video to police vehicle1: 1.9Mbits per second
- Police car low-resolution streaming video to police vehicle2: 1.9Mbits per second
- Helicopter high-resolution streaming video to police commander: 3.1 Mbits per second
- Helicopter high-resolution streaming video to SWAT commander: 3.1 Mbits per second
- Download of floor plans: 0.5 Mbits per second
- “Background” ongoing police activity: 0.1 Mbits per second

This gives us a 19.2 Mbits per second downlink data stream from the command center over the backhaul and down the LTE network. The total backhaul load imposed by these streaming video feeds is 25.5 Mbits per second. Note that the downloads of floor plans or other data requests are probably only a few megabytes each and would only last 10 or 20 seconds.

The following diagram illustrates both the projected bandwidth required for the incident and the bandwidth that is available on a 10 MHz (5 MHz by 5 MHz) system. Where the available bandwidth is inadequate it is highlighted in red (below the line indicating required bandwidth):



Barricaded hostage scenario bandwidth as measured and required

It should be obvious that this scenario exceeds the capabilities of the network we tested in almost every situation.

Suspected Bomb

A suspicious package turns out to be a bomb and must be deactivated. The bomb squad uses a remote-controlled robot to open the package and deactivate the explosive device. Civilian cellular telephone service is turned off in the area to foil remote activation. The police respond with the following mobile units:

- 1 helicopter
- 1 police incident commander
- 1 bomb squad commander
- 1 bomb squad remote control camera
- 1 police car camera
- 1 police vehicle receiving video feed

At the peak of the incident, we have the following data being uploaded to the LTE network:

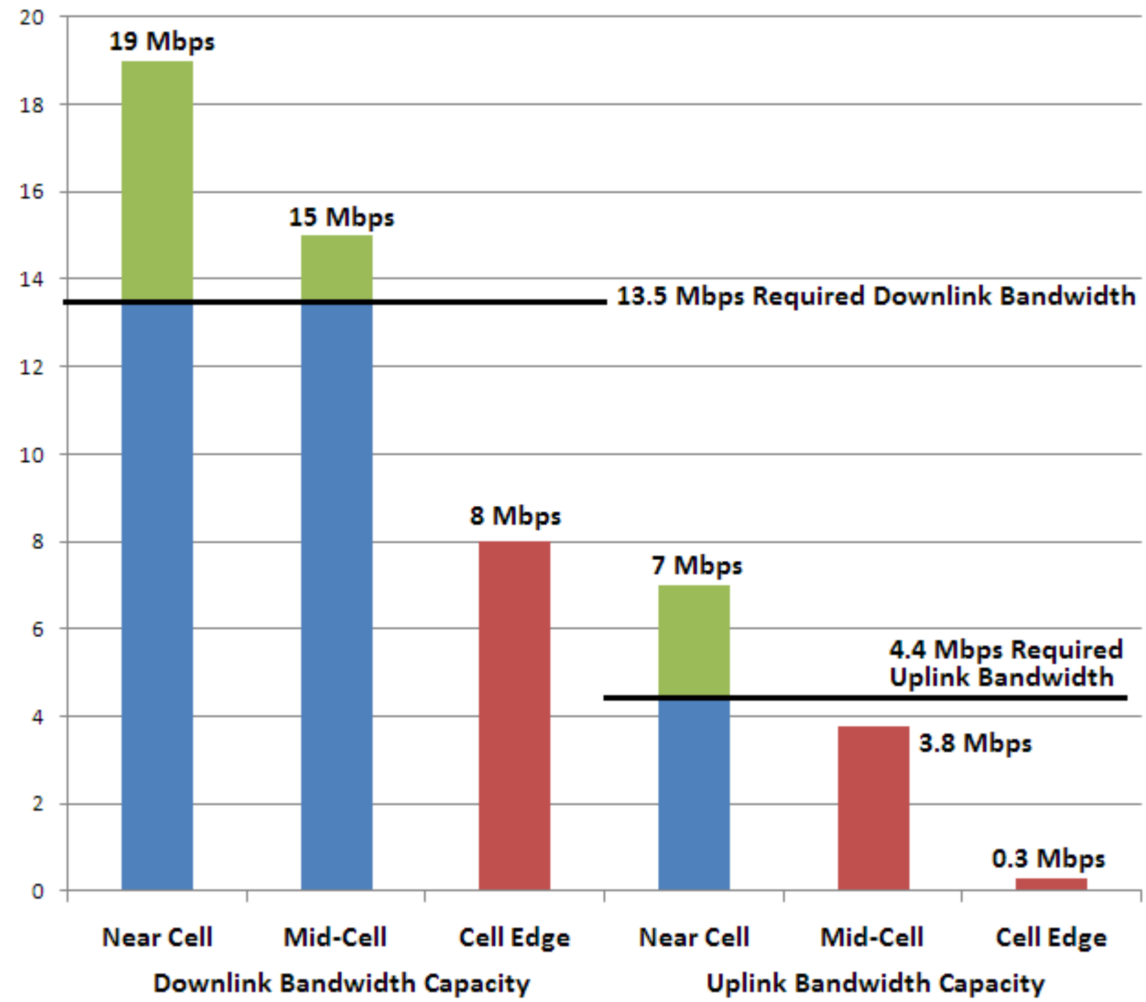
- Bomb squad remote control high-resolution streaming video: 3.1 Mbits per second
- Police car low-resolution streaming video: 1.2 Mbits per second
- “Background” ongoing police activity: 0.1 Mbits per second

This gives us a 4.4 Mbits per second uplink data stream to the LTE network and over the backhaul to the command center. We assume that the command center relays the helicopter stream, bomb squad remote control camera stream, and police vehicle stream to the bomb squad commander; the helicopter and squad car stream to the police commander; and the helicopter stream to a close-in police vehicle. This means the following data are downloaded over the LTE network:

- Helicopter high-resolution streaming video to police commander: 3.1 Mbits per second
- Helicopter high-resolution streaming video to bomb squad commander: 3.1 Mbits per second
- Bomb remote control camera high-resolution streaming video to bomb squad commander: 3.1 Mbits per second
- Police vehicle low-resolution streaming video: to police commander: 1.2 Mbits per second
- Police vehicle low-resolution streaming video: to bomb squad commander: 1.2 Mbits per second
- Helicopter high-resolution streaming video to police vehicle: 1.2 Mbits per second
- Download of utility plans of the neighborhood: 0.5 Mbits per second
- “Background” ongoing police activity: 0.1 Mbits per second

This gives us a 13.5 Mbits per second downlink data stream from the command center over the backhaul and down the LTE network. The total backhaul load imposed by these streaming video feeds is 17.9 Mbits per second. Note that the downloads of utility plans or other data requests are probably only a few megabytes each and would only last 10 or 20 seconds.

The following diagram illustrates both the projected bandwidth required for the incident and the bandwidth that is available on a 10 MHz (5 MHz by 5 MHz) system. Again, where the available bandwidth is inadequate it is highlighted in red (below the line indicating required bandwidth):



Suspected bomb scenario bandwidth as measured and required

It is clear that the test network can only support this scenario if it occurs very close to the cell site.

Public Safety Video and Data Requirements

The above scenarios do not account for any other types of applications that may be used or needed during these incidents but they clearly show that even under these conditions the 10 MHz of spectrum allocated to public safety is not sufficient to provide the video and data services that will be required during these types of incidents. These incidents are not events that happen once in a while within a given jurisdiction, these and other incidents that require multiple-unit response and the use of video and data for extended periods of time occur on a daily basis.

Note that the above scenarios do not include any voice service over LTE. If and when mission-critical voice does become available over LTE it will put additional stress on the broadband network, especially in confined areas, which is the case for most incidents. If we had added the bandwidth required for 30 push-to-talk devices into our testing scenarios, the amount of available bandwidth for video and data services would be reduced by 15-20% (based on current estimates within the LTE technology community). Thus the public safety network needs to have enough spectrum available to be able to provide the types of video and data services required as well as to be able to add mission-critical voice services if they become available.

Public demand for broadband services has grown more than 75% each year for the past three years, yet if you had asked prior to commercial broadband being available what the demand for wireless broadband services would be, the answer, three years ago, would not have anticipated this huge rate of growth due to the advancement of smartphones and tablets as well as the proliferation of applications. This same growth curve will apply to the public safety community as well. Until the network is built and placed into operation we can only identify the most obvious of applications and services. However, once the network is online, just as in the commercial world, public safety will find additional uses and applications for the broadband network that will not only drive up daily demand and usage but also drive up the amount of bandwidth that will be consumed during these types of incidents. Therefore, to limit the public safety community to 10 MHz of broadband spectrum will not meet its needs on a daily basis nor will it allow for new and innovative applications that can be used to better serve the pubic and protect the lives of first responders as well.

What Public Safety Can Count On in 10 MHz of Spectrum

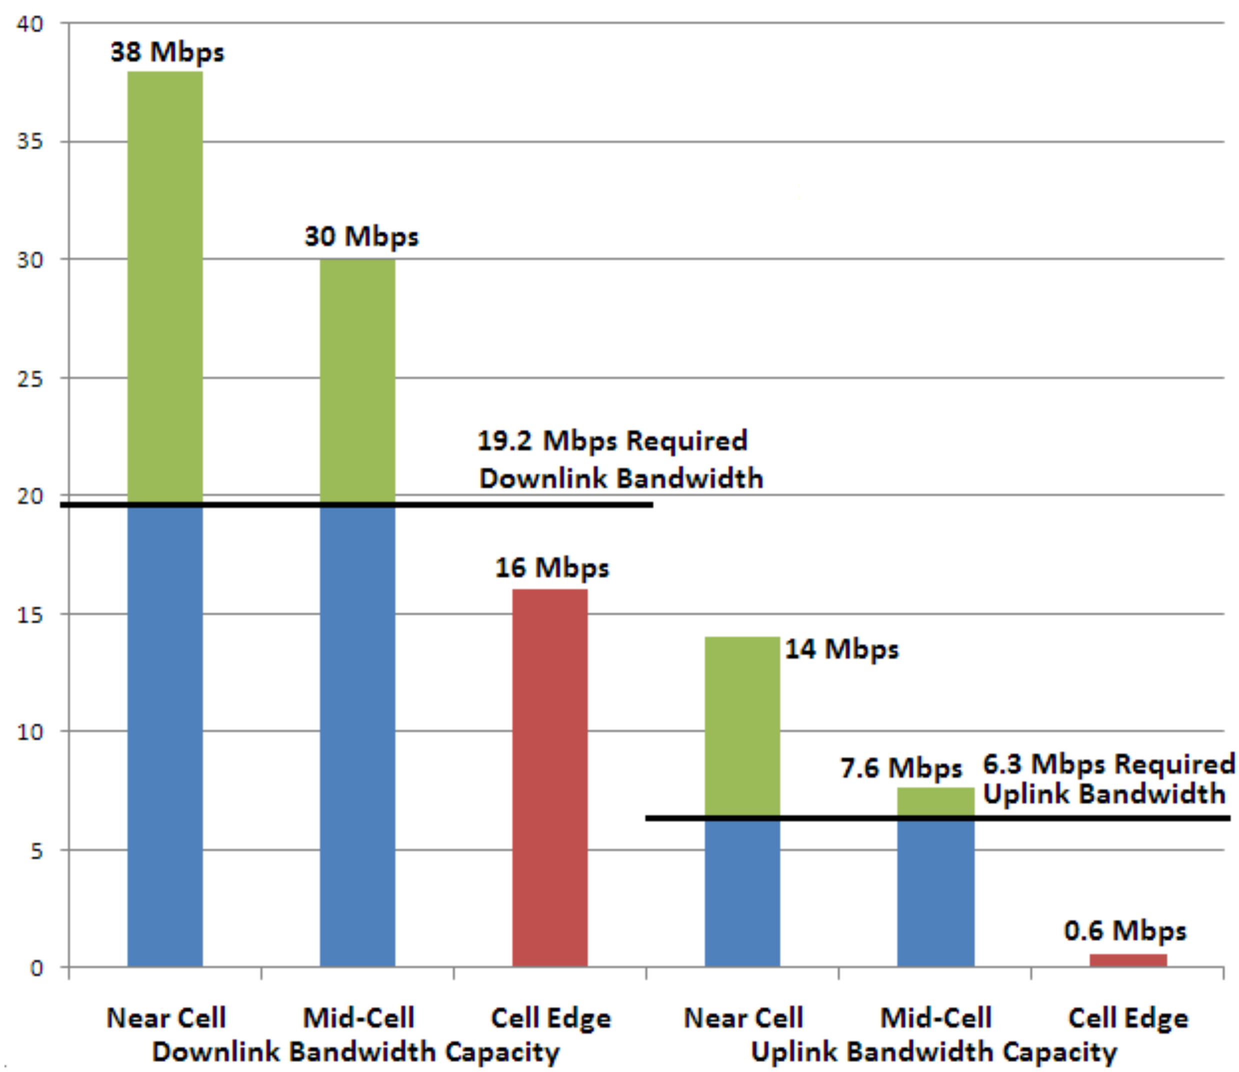
As described above, the tests were conducted with the minimum expected response to an incident. As incidents escalate, response levels will increase and the demand for data and video services will increase as well. As can be seen by the test results, additional demand would create network overload in every condition and at every location within a cell sector.

During a major incident, once an incident command center has been established it will be possible to interactively manage the demand for data and video, but the demand will outstrip the network's ability to meet that demand. Well before an incident command post is established at the scene, the demand for data services will be such that the network will quickly reach saturation and become non-functional. As we observed, when the network is overloaded, the impact of the overload was not only to block the subsequent video or data stream but also to cause the videos or data streams that had been usable to become unusable.

Public safety will be able to rely on a 10-MHz network during the initial phase of the incident and perhaps again once a command structure has been established. However, during the most critical portion of the response as more first responders arrive on the scene and when the agency's command center is in an information gathering mode, the system will reach saturation and not be able to provide the critical data needed to contain the incident. Incidents can and do grow rapidly in size and complexity, and it is crucial to those in the field as well as those within the command structure to have real-time video and data services available to them during the entire incident, not only at the beginning.

How Much Spectrum Is Required?

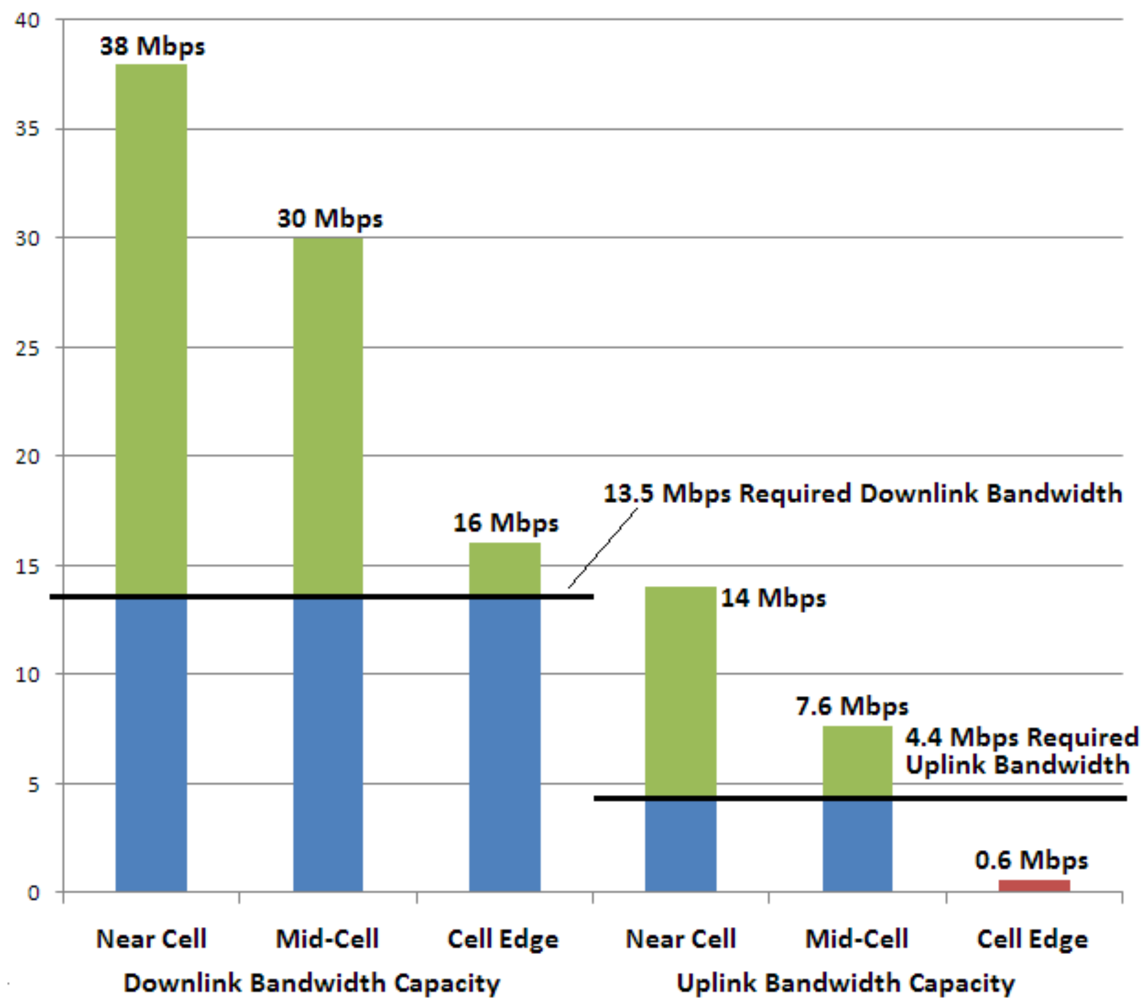
As described above, the tests demonstrate that 10 MHz of spectrum is inadequate to support the needs of the public safety community. The obvious question then is if 10 MHz is too little, how much is enough? While we do not have a 20-MHz network to test, we can project its performance. The following diagram illustrates how 20 MHz of contiguous spectrum would perform in the barricaded hostage scenario. Again, where the available bandwidth is inadequate it is highlighted in red (below the line indicating required bandwidth):



Barricaded hostage scenario bandwidth as projected and required

The projected 20 MHz (10 MHz by 10 MHz) network has sufficient capacity for this demanding scenario in all locations except at the very edge of the cell sector coverage. Edge of cell communications is an issue with both commercial and public safety networks. It will be critical for the network to be designed to minimize the edge of cell situations within a given coverage area. This can be accomplished with overlapping cell coverage but at the same time care must be taken to minimize the interference between overlapping cells. After the initial network completion it will be necessary to drive test the network to ensure that sufficient bandwidth is available, especially within major metro areas. Ensuring that there is sufficient bandwidth could add to the overall cost of this network.

The following diagram illustrates how 20 MHz of contiguous spectrum would perform in the suspected bomb scenario:



Suspected bomb scenario bandwidth as projected and required

The 20 MHz (10 MHz by 10 MHz) network has sufficient capacity for this demanding scenario in all locations except at the very edge of the cell sector coverage, and that for uplink only. Again, system design will be critical to ensure that edge of cell situations are minimized whenever possible.

Conclusions

We believe that the tests conducted using the Cornerstone network provide the first real-world results for a 10-MHz public safety broadband system. After vetting the incidents chosen prior to the testing and vetting the results of the testing with seasoned first responders and commanders, it is clear to us that 10 MHz of spectrum will not meet the daily incident requirements of the public safety community.

Some detractors might try to point out that some broadband is better than none. However, this is not the case since at the most crucial times network overload can and does result in the entire system not being available for use. During the recent earthquake on the east coast, the commercial networks were fully operational but they were overloaded. The result was not only that those who wanted to make a call or send video were denied access to the network, but many who had network connectivity lost that connectivity—a situation that is intolerable for public safety.

The public safety voice networks are built to meet harsh standards, and the broadband network must be designed and built to those same mission-critical standards. Not having enough capacity available for the network is not an acceptable option. Neither is expecting the commercial operators to provide priority access to the first responder community. Again, during the east coast earthquake not only were the networks overloaded, the signaling channel used by devices to communicate their requests for service was overloaded. In that circumstance, even if priority had been granted to public safety, the devices would not have been able to communicate that priority status with the network and would not have had access to the network.

Public safety needs a dedicated, nationwide broadband network. The network must be robust and it must have sufficient bandwidth available within a single cell sector. Our findings clearly show that 10 MHz of spectrum and the bandwidth it provides does not meet these criteria. More spectrum is needed and it must be contiguous to the existing public safety broadband spectrum, not in some other portion of the spectrum and not allocated after the public safety broadband network is in operation. To add spectrum that is not adjacent to the existing broadband spectrum would more than double the cost of the network and would increase the cost of the devices used on the network.

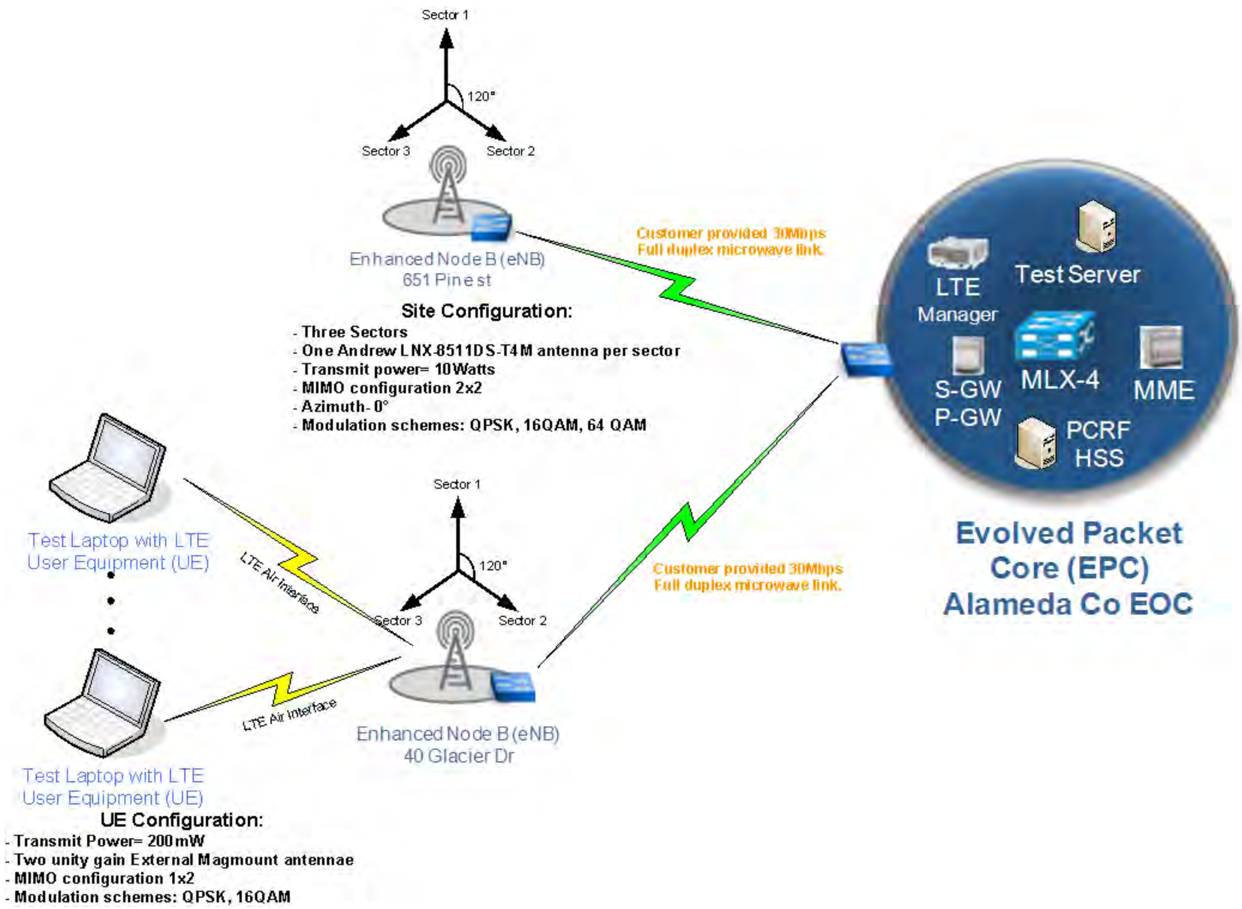
Based on these real-world tests, we strongly recommend that public safety be provided with at least 20 MHz of contiguous spectrum (10 MHz by 10 MHz). The only way to accomplish this is to reallocate the 700-MHz D Block to public safety and this should be done prior to the build-out of the waiver recipients' portion of the nationwide network. The cost to build out 10 MHz of spectrum and 20 MHz of spectrum is identical at the time of construction. Later, the addition of this spectrum would add to the cost of the network and require device redesign, adding to the cost of the user equipment. The entire premise of providing public safety with broadband spectrum using a commercial technology is to provide public safety personnel with capabilities they do not have presently at a lower cost than its existing voice communications equipment.

The public safety nationwide interoperable broadband network based on 10 MHz of spectrum that is currently available will not meet the needs of the public safety community. Rather it will, on a daily basis, end up congested at incident locations and fail to provide the public safety community with the bandwidth that is needed for data, pictures, and video. Most emergency incidents are confined to a small geographic area and, as noted above, our testing results conclude that the current bandwidth assigned to public safety is not sufficient even for incidents that occur on a daily basis.

If, in the future, mission-critical voice is added to this network, it will further degrade the amount of available bandwidth. The demand for voice, data, and video all within the same cell sector will swamp the network's capacity and even with Quality of Service and priority status enabled, the public safety community will not have enough bandwidth to provide the mission-critical level of service required. Public safety cannot afford to rely on a network that will not provide the amount of bandwidth it needs when it needs it. We therefore recommend that the additional 10 MHz of bandwidth that is adjacent to the public safety spectrum be reallocated to public safety in a timely manner.

Appendix A: Network Details

The network under test was configured in this manner:



Motorola, the network system supplier, stated that the network was configured with a 30-Mbps backhaul bandwidth:

- Not limited to eNodeB sector or user device
- Available on a first come, first served basis
- Full 30 Mbps can be assigned to a single user device

The bottom line is that the backhaul did not create a network chokepoint. Also, note that none of the tests transmitted data over the Internet.

The cell site power output and effective radiated power are as follows:

- Full power output of the system is 80 Watts (2 x 40 Watts max) and the corresponding ERP (with conservative estimates on line losses) is 56.9dBm

- FCC Experimental License limits to 59.4 Watts max ERP. To abide by this limitation, the power on the eNb has been turned down to 10 Watts total, which corresponds to about 59.4 Watts ERP.

To explain further:

Tx Power = 10W = 40 dBm
Antenna Gain = 14 dBi
Cable + Connectors Loss = 4 dB*
EIRP = 40 + 14 – 4 = 50 dBm
ERP = EIRP – 2.1dB = 47.9 dBm

This is almost right at the FCC Experimental License ERP limit of 59.4W = 10*log10(59.4x1000) = 47.7dBm.

At the Glacier Street site, pictured below, the LTE antennas (circled) are co-located on a tower hosting public cellular antennas as well as microwave antennas:

LTE Antenna location at the Glacier Street site

In downtown Martinez at 651 Pine Street the LTE antennas are located on top of the tallest building in the area:

LTE Antennas at 651 Pine Street

The network core and our test server were located at the Contra County Emergency Operations Center:

Microwave dishes at EOC network core and test server location

Appendix B: Testing Methodology

Test Locations

We tested at three different sites in the Martinez, California area. The Glacier Street site was adjacent to the LTE base station at the center of the cell sector; our test location was 0.1 miles from the base station. This gave us the best possible signal strength, and thus the maximum data throughput over the air. In other words, this was the “best case” network performance.

Below is a photograph of the Glacier Street site, showing the location of the cell tower and the test site:

The Sunvalley Mall is located in the center of the cell sector at the midpoint of the base station's coverage map, 2.23 miles from the tower. We characterize this site as giving us "typical" network performance.

Below is a photograph showing the cell tower in the upper left corner and the Sunvalley Mall test site in the lower right corner:

The final site is at the John Muir House National Monument, 2.35 miles from the tower. Even though this location is only slightly farther from the tower than the Sunvalley Mall site, intervening hills place it at the edge of the base station's coverage area. Therefore this site gives us a measure of "worst case" performance.

Below is a photograph showing the cell tower at the right and the test location at the left. The area in the center contains hills that block line of sight between the tower and the test location:

Test Procedures and Tools

At each site we streamed data from the network core to the client computers ("download" tests) and streamed data from the client computers to the core ("upload" tests). We also streamed test videos in each direction. For both data and video we streamed to a single client and simultaneously to multiple clients. Likewise, we performed upload tests to the server from both single and multiple clients.

We used seven client computers during the tests. Each was a Panasonic Toughbook CF-30 with a 1.6-GHZ Intel Core 2 Duo CPU and 2 GB of memory running Microsoft Windows XP with Service Pack 3. Attached to the client computers was a pre-production external USB LTE modem. At the network core we installed a server computer that was powered by a 2.66-GHZ Intel Core i5 processor and 4 GB of memory, running Windows 7 Professional 32-bit. Since the server was located at the network core, we never relied on an Internet connection for any of the data traffic.

Several different software packages were used to conduct the tests:

VLC media player, available at videolan.org, was used to stream and display the test videos. VLC is a free and open source cross-platform multimedia player and framework that plays most multimedia files as well as DVD, audio CD, VCD, and various streaming protocols.

Wireshark, available at wireshark.org, was used to measure the data traffic generated by streaming the test videos. Wireshark is the world's foremost network protocol analyzer. It captures and allows interactive browsing of traffic running on a computer network. It is the *de facto* (and often *de jure*) standard across many industries and educational institutions.

Iperf, available at sourceforge.net/projects/iperf, was used to stream and measure data traffic. Iperf was developed by NLANR/DAST as a modern alternative for measuring maximum TCP and UDP bandwidth performance. Iperf allows the tuning of various parameters and UDP characteristics and reports bandwidth, delay jitter, and datagram loss.

We ran two types of tests: data streaming and video streaming.

In the data streaming tests we used Iperf to stream random data via UDP, sending 1470-byte data packets. As explained above, UDP is the carrier protocol for streaming video, so streaming UDP packets is a valid stand-in for streaming video. As well as performing the streaming, Iperf generated comprehensive logs that enabled us to accurately characterize the end-to-end network performance.

We used a webcam to record a video while driving through Martinez, California. The video was recorded on one of the Panasonic Toughbooks with VGA resolution (640 by 480 pixels). Because of the limited processing power of the Toughbook, the recorded video was captured at about 15 to 20 frames per second and exhibited the occasional dropped frame on playback. Streaming the test video on a computer with a 2.3-GHz Intel Core i5 processor produces an outbound bit rate of 1.91 Mbits per second.

In the video streaming tests we used VLC to stream a test video to a particular client computer using the Real-time Transport Protocol (RTP), which defines a standardized packet format for delivering audio and video over IP networks. RTP is used extensively in communication and entertainment systems that involve streaming media and it is designed for end-to-end, real-time transfer of streaming data. The protocol provides facility for jitter compensation and detection of out of sequence arrival in data that are common during transmissions on an IP network. RTP is regarded as the primary standard for audio/video transport in IP networks.

Real-time multimedia streaming applications require timely delivery of information and can tolerate some packet loss to achieve this goal. Thus the majority of the RTP implementations are built on the User Datagram Protocol (UDP) rather than on the Transmission Control Protocol (TCP), commonly used for email, file transfer, and web browsing. However, too many lost packets result in dropped video frames, lost pixels, and image freezing.

Appendix C: Data Test Results

The following tables present the raw data from the field tests. The columns display the following information:

Mbits/sec	is the rate at which data was received by the target computer (client computer on downloads, server computer on uploads) measured in megabytes (not megabits) per second of data delivered.
Jitter	is the average of the deviation from the network mean packet latency across the network, measured in milliseconds.
Lost Data	is the percentage of sent data that was not received by the target computer.
Antenna	indicates whether the field computer's LTE modem is connected to an external antenna or is relying on an antenna internal to the modem. During the tests we found the modems with external antennas to perform significantly better than those with internal antennas.
Test	summarizes the particular test for which the results are displayed. If the test mentions more than one client, it means that data was being sent to or received from multiple computers at the same time.

Glacier Street (near cell) Downlink Tests

The first test set below demonstrates the maximum capacity of the network at the "best case" location. We streamed data to a mobile unit at a rate of 50 Mbits per second, well above the network capacity. As expected, only a fraction of the packets were received. We repeated the test twice more at a lower rate of 20 Mbits per second, for an average capacity of slightly less than 16 Mbits per second.

The next two test sets demonstrate that at 10 Mbits per second the network is highly reliable with very few lost packets, and at 5 Mbits per second no packets are lost.

Following that, the next two tests show the limits of the network: Streaming to three mobile units at 5 Mbits per second shows that more than 25% of the data packets are lost. The final test shows that performance will vary, as we were able to stream data to four mobile clients at 5 Mbits per second with negligible packet loss.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
15.40	2.77	69%	External	Download at 50 Mbits/sec to 1 client
14.60	1.78	3%	External	Download at 20 Mbits/sec to 1 client
17.00	1.86	15%	External	Download at 20 Mbits/sec to 1 client
15.67	1.82	9%	External	Average Mbits/sec
9.97	1.39	0%	External	Download at 10 Mbits/sec to 1 client
9.83	2.32	2%	External	Download at 10 Mbits/sec to 1 client
9.90	1.85	1%	External	Average Mbits/sec
5.00	2.03	0%	External	Download at 5 Mbits/sec to 1 client

4.74	2.13	1%	Internal	
18.99				Total Mbits/sec

Eleven attempts were made to simultaneously download data at 5 Mbits/sec to four clients. Unfortunately, only one of these tests completed (and as noted above, with almost no dropped packets). During the other ten tries one or more of the modems dropped the network connection.

Glacier Street (near cell) Uplink Tests

In the first test set below we streamed data to from a mobile unit at a rate of 100 Mbits per second, well above the network capacity. As expected, only a fraction of the packets were received. The average capacity of the network was somewhat less than 6 Mbits per second.

The second test set shows that at an upload rate of 5 Mbits per second the network is highly reliable with no lost packets.

The next two test sets demonstrate the difference between a modem with an internal antenna and one connected to an external antennal. The mobile units with external antennas were able to stream data to the server at a higher data rate, with fewer lost packets.

The final two tests show the limits of the network: Streaming from multiple mobile units at 5 Mbits per second each resulted in significant packet loss.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
6.25	8.52	90%	External	Upload at 100 Mbits/sec from 1 client
5.44	3.68	92%	External	Upload at 100 Mbits/sec from 1 client
5.85	6.10	91%	External	Average Mbits/sec
5.00	4.31	0%	External	Upload at 5 Mbits/sec from 1 client
4.99	3.72	0%	External	Upload at 5 Mbits/sec from 1 client
5.00	4.01	0%	External	Average Mbits/sec
5.75	3.57	42%	External	Upload at 10 Mbits/sec from 1 client
5.70	5.92	43%	External	Upload at 10 Mbits/sec from 1 client
5.49	3.82	8%	External	Upload at 10 Mbits/sec from 1 client
5.65	4.44	31%	External	Average Mbits/sec
2.20	6.07	78%	Internal	Upload at 10 Mbits/sec from 1 client
4.40	7.62	56%	Internal	Upload at 10 Mbits/sec from 1 client
4.21	5.16	58%	Internal	Upload at 10 Mbits/sec from 1 client
4.35	3.37	27%	Internal	Upload at 10 Mbits/sec from 1 client
3.79	5.55	55%	Internal	Average Mbits/sec
2.98	9.02	40%	External	Upload at 5 Mbits/sec from 2 clients
3.57	4.17	29%	External	
6.55				Total Mbits/sec
2.12	11.13	57%	External	Upload at 5 Mbits/sec from 3 clients
2.52	5.54	49%	External	
2.44	4.67	51%	External	
7.08				Total Mbits/sec

As with the download tests reported above, we were unable to upload data from more than three clients simultaneously since none of these tests completed. One or more of the modems dropped the network connection.

Glacier Street (near cell) Simultaneous Downlink / Uplink Tests

These tests confirm what we observed in the separate download and upload tests above. Since the downlink and uplink operate on different frequencies, they are independent of each other, and that is what we measured. Also, these tests show the lower performance of the modems with internal antennas.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
5.00	1.60	0%	External	Download at 5 Mbits/sec to 2 clients, upload at 5 Mbits/sec from 2 clients
4.97	2.98	1%	External	
9.97				Total Download Mbits/sec
1.00	5.95	0%	Internal	
2.87	8.04	42%	Internal	
3.87				Total upload Mbits/sec
4.99	3.21	0%	External	Download at 5 Mbits/sec to 3 clients, upload at 5 Mbits/sec from 2 clients
4.97	2.98	1%	External	
4.99	3.15	0%	External	
14.95				Total Download Mbits/sec
1.00	8.86	0%	Internal	
1.94	5.53	61%	Internal	
2.94				Total upload Mbits/sec

Beyond these tests, five attempts were made to simultaneously download data to four clients while uploading from two others. Unfortunately, none of these tests completed. One or more of the modems dropped the network connection.

Sunvalley Mall (mid cell) Downlink Tests

The first test set below demonstrates the maximum capacity of the network at the "typical case" location. We streamed data to a mobile unit at data rates ranging from 20 Mbits per second, well above the network capacity, down to 10 Mbits per second. The average capacity measured was slightly less than 11 Mbits per second. Note that at a streaming rate of 10 Mbits per second, only 1% of the data packets were lost.

The next two test sets demonstrate the difference between a modem with an internal antenna and one connected to an external antennal. The mobile units with external antennas were able to receive data from the server at a higher data rate, with fewer lost packets.

The final two test sets demonstrate that at 5 Mbits per second the network is highly reliable and able to stream to three clients simultaneously with few if any lost packets.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
11.10	2.23	44%	External	Download at 20 Mbits/sec to 1 client
11.10	2.20	26%	External	Download at 15 Mbits/sec to 1 client
9.76	2.03	35%	External	Download at 15 Mbits/sec to 1 client
11.10	2.30	21%	External	Download at 14 Mbits/sec to 1 client
12.50	5.04	4%	External	Download at 13 Mbits/sec to 1 client
11.30	1.57	6%	External	Download at 12 Mbits/sec to 1 client
9.89	0.70	1%	External	Download at 10 Mbits/sec to 1 client
10.96				Average Mbits/sec
4.60	4.29	7%	Internal	Download at 5 Mbits/sec to 1 client
4.96	4.88	1%	External	Download at 5 Mbits/sec to 2 clients
2.45	5.16	51%	Internal	
7.41				Total download Mbits/sec
4.97	2.50	1%	External	Download at 5 Mbits/sec to 2 clients
4.98	0.55	0%	External	
9.95				Total download Mbits/sec
4.97	4.44	1%	External	Download at 5 Mbits/sec to 3 clients
4.97	4.62	1%	External	
4.98	0.83	0%	External	
14.92				Total download Mbits/sec

Two attempts were made to simultaneously download data at 5 Mbits/sec to four clients. Unfortunately, none of these tests completed. One or more of the modems dropped the network connection.

Sunvalley Mall (mid cell) Uplink Tests

In these tests we streamed data from one and then two mobile units at a rate of 5 Mbits per second, which turned out to be well above the network capacity. Thus only a fraction of the packets were received. The measured capacity of the network was slightly more than 2 Mbits per second.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
0.85	27.76	83%	External	Upload at 5 Mbits/sec from 1 client
0.75	36.15	85%	External	Upload at 5 Mbits/sec from 2 clients
1.36	8.22	72%	External	
2.11				Total upload Mbits/sec

Three additional attempts were made to stream data to the host, but the modems disconnected before the tests could be completed.

Sunvalley Mall (mid cell) Simultaneous Downlink / Uplink Tests

These tests confirm what we observed in the separate download and upload tests above. We were able to stream from the server to the mobile units at a total rate of almost 10 Mbits per second while simultaneously uploading at 1 Mbit per second.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
4.98	5.18	5%	External	Download at 5 Mbits/sec to 2 clients, upload at 5 Mbits/sec from 1 client
4.98	0.00	2%	External	
9.96				Total download Mbits/sec
1.02	21.11	79%	External	Total upload Mbits/sec

John Muir House (cell edge) Download Tests

Because this location is at the edge of the LTE cell coverage, the modems with internal antennas were unable to make a connection to the network, thus we were unable to run all of the planned tests.

The first two test sets below demonstrate the maximum capacity of the network at the “worst case” location. We streamed data to a mobile unit at data rates ranging from 15 Mbits per second, well above the network capacity, down to 10 Mbits per second. The average capacity measured was slightly less than 11 Mbits per second. Note that at a streaming rate of 5 Mbits per second, only 4% of the data packets were lost.

The last two test sets demonstrate that the network cannot support streaming to more than one mobile client at 5 Mbits per second without suffering significant data packet loss.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
6.08	3.19	59%	External	Download at 15 Mbits/sec to 1 client
6.05	3.21	49%	External	Download at 12 Mbits/sec to 1 client
5.99	3.53	40%	External	Download at 10 Mbits/sec to 1 client
6.04				Average Mbits/sec
4.88	3.59	4%	External	Download at 5 Mbits/sec to 1 client
3.26	6.79	35%	External	Download at 5 Mbits/sec to 2 clients
4.32	0.58	14%	External	
7.58				Total download Mbits/sec
2.13	4.22	57%	External	Download at 5 Mbits/sec to 3 clients
2.84	7.66	43%	External	
3.14	3.44	37%	External	
8.11				Total download Mbits/sec

Two attempts were made to simultaneously download data at 5 Mbits/sec to four clients. Unfortunately, none of these tests completed. One or more of the modems dropped the network connection.

John Muir House (cell edge) Upload Tests

In these tests we streamed data from a mobile unit at a rate of 10 and then 5 Mbits per second, which turned out to be well above the network capacity, thus only a fraction of the packets were received. The measured capacity of the network was slightly more than 0.2 Mbits per second.

Mbits/sec	Jitter (ms)	Lost Data	Antenna	Test
0.19	67.35	98%	External	Upload at 10 Mbits/sec from 1 client
0.19	70.20	96%	External	Upload at 5 Mbits/sec from 1 client
0.27	47.86	95%	External	Upload at 5 Mbits/sec from 1 client
0.22				Average Mbits/sec

Appendix D: Video Test Results

The following tables present the raw data from the field tests. The columns display the following information:

Mbits/sec	is the rate at which data was received by the target computer (client computer on downloads, server computer on uploads) measured in megabytes (not megabits) per second of data delivered.
Jitter	is the average of the deviation from the network mean packet latency across the network measured in milliseconds.
Lost Data	is the percentage of sent data that was not received by the target computer.
Antenna	indicates whether the field computer's LTE modem is connected to an external antenna or is relying on an antenna internal to the modem. During the tests we found the modems with external antennas to perform significantly better than those with internal antennas.
Test	summarizes the particular test for which the results are displayed. If the test mentions more than one client, it means that data was being sent to or received from multiple computers at the same time.

Note that some of the tests do not have the data rates recorded due to a software failure on the mobile units.

Downlink Tests

In these tests we streamed our test video to one or more mobile units. We recorded the received video image and later checked it for quality. When the received video is labeled "good quality" it means a reasonable image is displayed, although some dropped frames are noticeable.

Location	Mbits/sec	Lost Data	Antenna	Test
Glacier Street	1.86	3%	External	Stream to client – good quality
	5.73			Stream to 3 clients – good quality
	7.64			Stream to 4 clients – good quality
	9.55			Stream to 5 clients – good quality
				Stream to 6 clients – modems disconnect
Sunvalley Mall	5.73			Stream to 3 clients – good quality
				Stream to 4 clients – modems disconnect
John Muir House	1.76	8%	External	Stream to client – good quality
John Muir House	1.60	16%	External	Stream to 2 clients – good quality
	1.42	26%	External	
	3.02		External	Total Mbits/sec
John Muir House	1.71	10%	External	Stream to 3 clients – good quality
	1.28	33%	External	
	1.81	5%	External	
	4.80			Total Mbits/sec
John Muir House				Stream to 4 clients – modems disconnect

Uplink Tests

In these tests we streamed our test video from one or more mobile units to the server. We recorded the received video image and later checked it for quality. When the received video is labeled "good quality" it means a reasonable image is displayed, although some dropped frames are noticeable.

Location	Mbits/sec	Lost Data	Antenna	Test
Glacier Street	1.67	13%	External	Stream from client – good quality
Sunvalley Mall	0.93	51%	External	Stream from client – image breakup
	3.82			Stream from 2 clients – good quality
				Stream from 3 clients – image breakup

Several attempts were made to stream more than one video simultaneously to the server at the Glacier Street test location, but none were successful. We were unable to successfully stream any videos from the mobile units to the server at the "worst case" John Muir House test site. The available network bandwidth was inadequate.

Appendix E: Anritsu Test Data

The following are images taken off the screen of the Anritsu LTE broadband test sets used during the tests. Each of these represents a snapshot in time and each includes a total of 520 Resource Blocks, 16 of which are used for signaling between the network and the device, leaving a total of 504 resource blocks allocated for data transfer.

The downlink and uplink each contain the same number of resource blocks; these screen shots are for the downlink only. The color of the resource block indicates the signal strength of the received signal. The lower numbers (i.e., closer to -0) indicate a stronger signal. As the signal weakens the numbers will move lower, i.e., -50, -89, etc. See the color grid within each screen shot to indicate the signal strength for each resource block. Black indicates that that resource block is empty and therefore available.

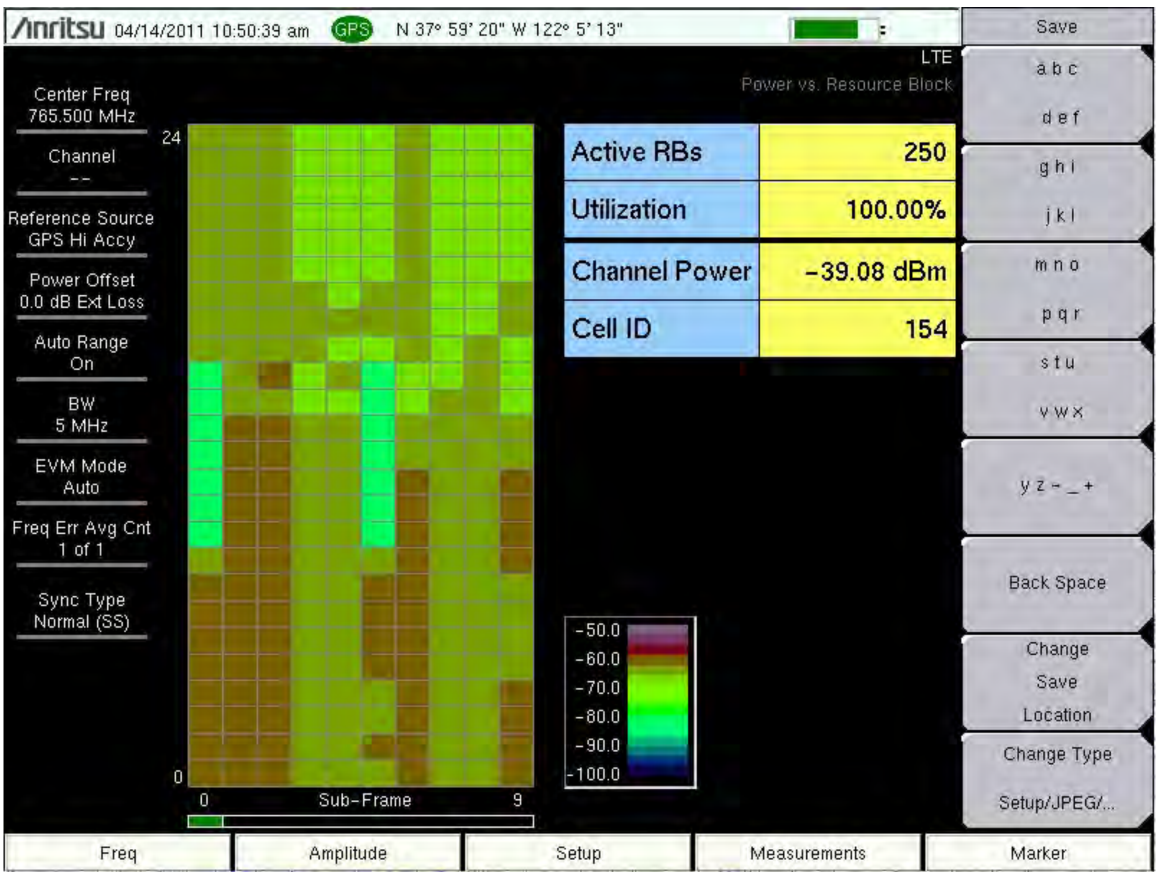

Diagram 1: Closest to the cell center, very strong signal, network is operating at 100% of its capacity

Notice in this diagram that the 16 signaling channel resource blocks as well as a few others in this frame are not in use.

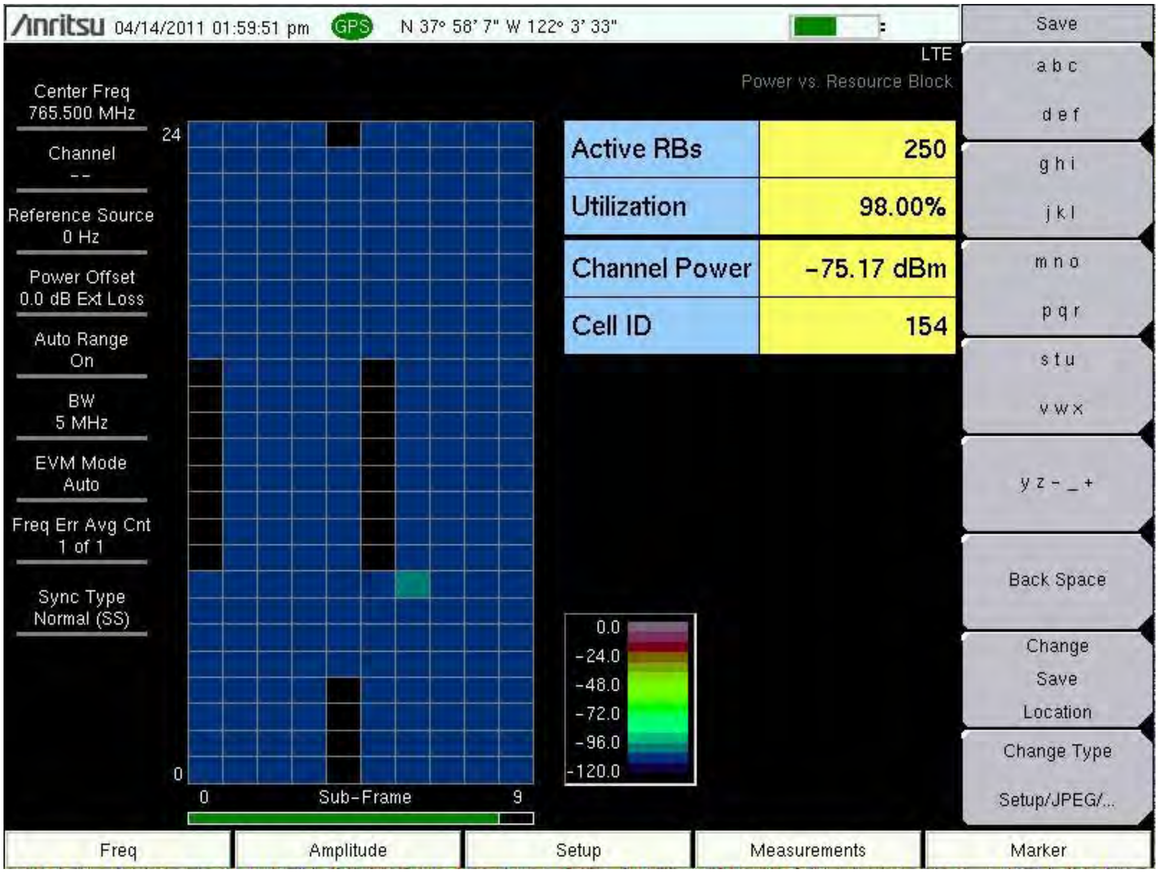

Diagram 2: Middle of cell coverage, signal level weaker, 98% network utilization

In the next diagram, notice that signal strength is much weaker and unevenly distributed within the resource block.

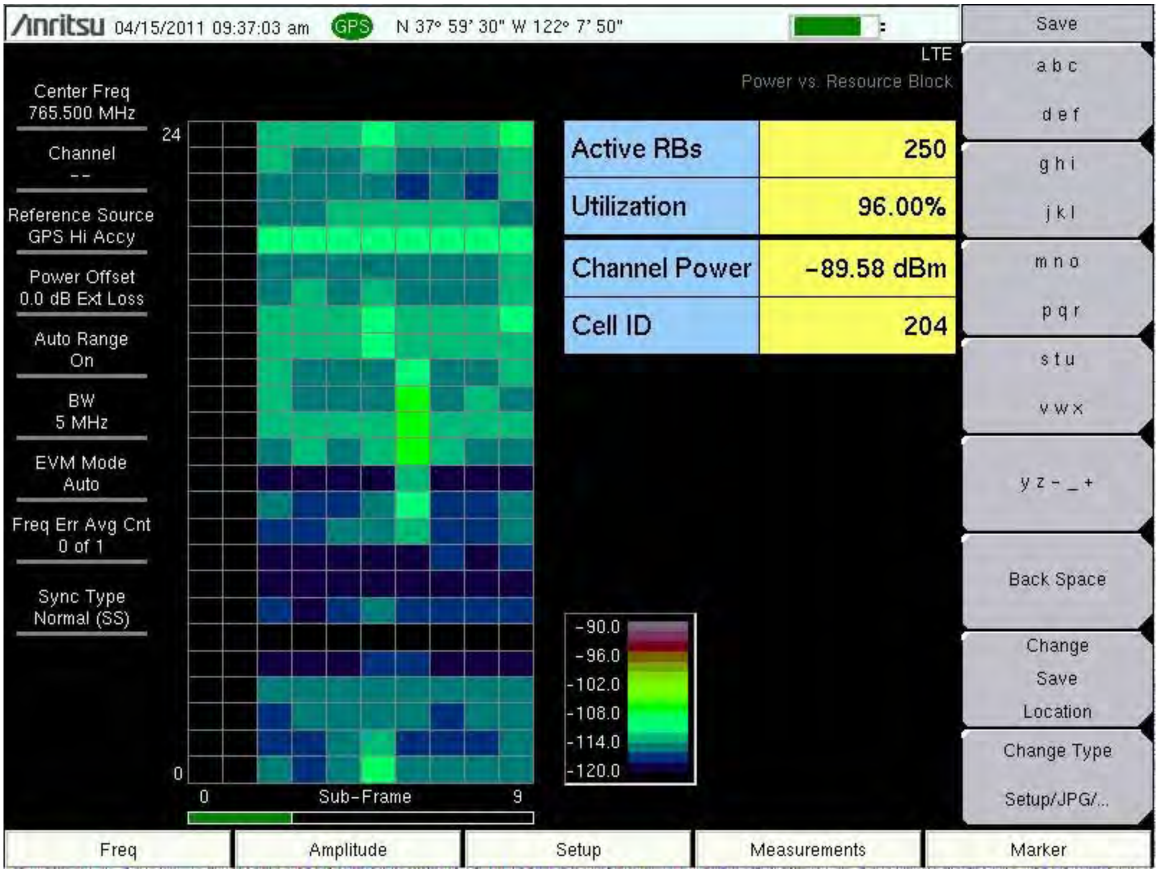

Diagram 3: Edge of cell, 96% system utilization

Appendix F: Test Logs

In this section we list a sample Iperf report from each of the three test sites.

Glacier Street (near cell)

This log documents the server sending data to a single client at the rate of 20 megabits per second:

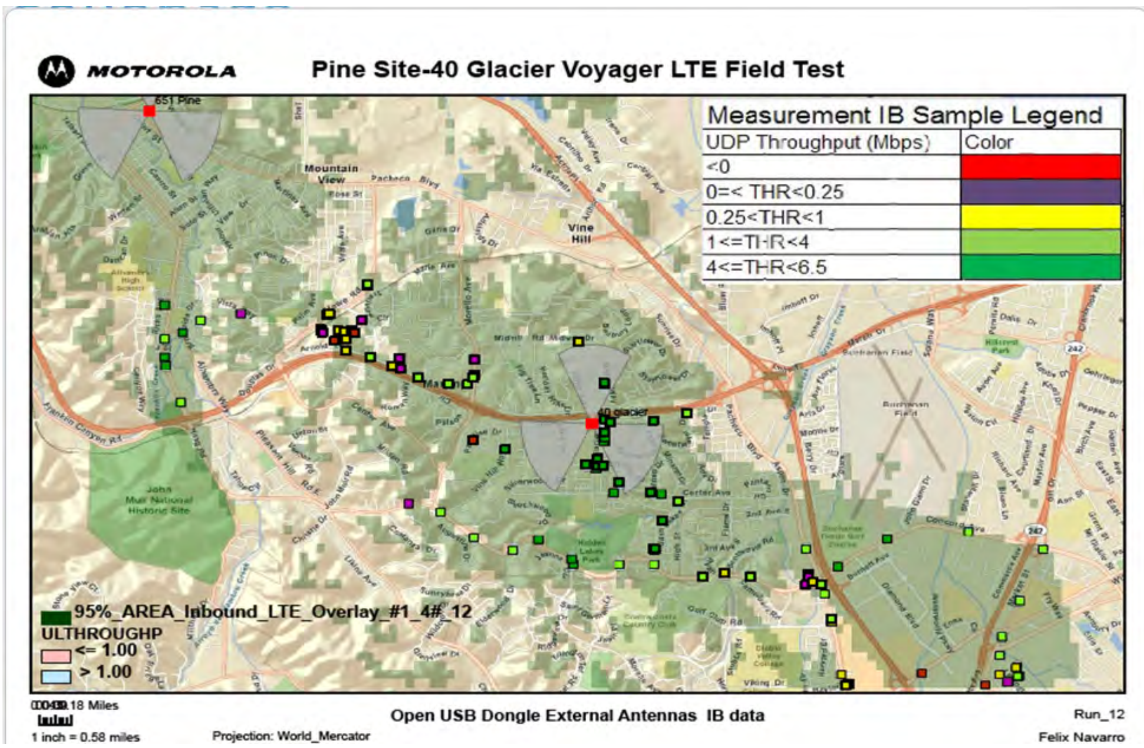
The following companies and organizations provided support and/or equipment for these tests and we are grateful for their contribution:

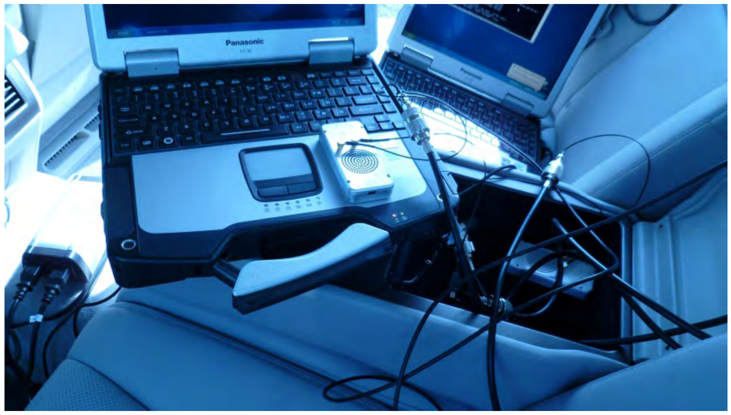
Motorola Solutions

Motorola, which provided the system under test, was gracious in the time and personnel it provided before, during, and after the tests. In addition, its initial drive tests of the network enabled us to determine the best test locations within the cell sector.



Panasonic

Panasonic loaned us seven Toughbook computers (model CF 30) in order to provide a consistent set of test devices. Each of these notebooks was running the same version of Windows XP. These notebooks are the same as those used by many public safety agencies in the United States and around the world.

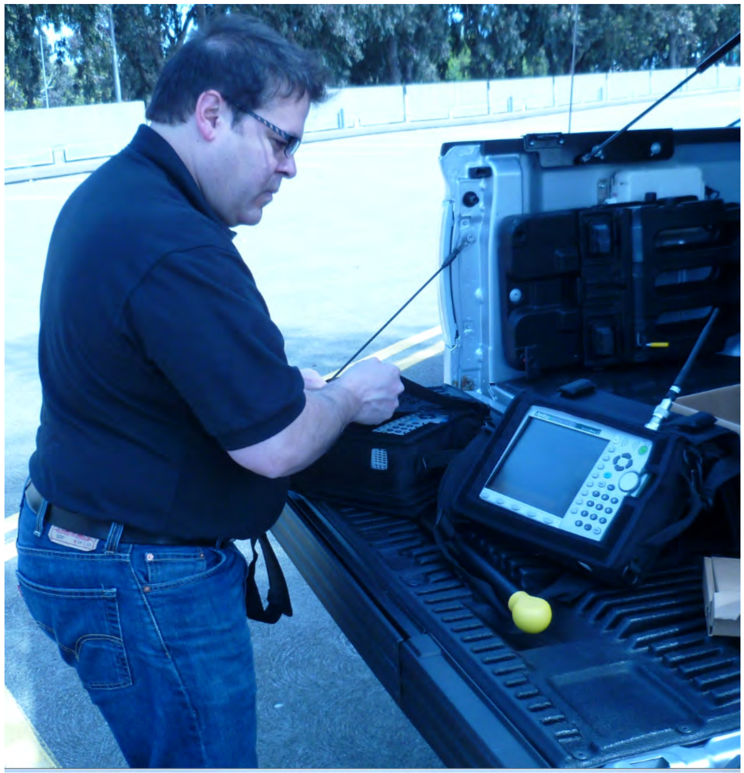


Two Toughbooks during the testing.

Toughbook displaying the test video.

Anritsu America

Anritsu America provided personnel, test equipment, and the latest version of its test software. Anritsu also verified our findings during the entire test period.



Anritsu America performing network measurements

Proposed Private/Public Partnership for Broadband Deployment

Results in Near 100% 9opulation Coverage and Higher Data Speeds

One business model that has been proposed for other states where the rural population does not have access to broadband services is as follows:

1) The Public Safety Governance organization (the license holder), enters into a public/private partnerships with interested parties to build-out the 700-MHz Public Safety broadband network in the state.
2) The private companies involved could include private telecommunications companies, local power utilities, health care and educational organizations.
3) The private companies would help fund the cost of the network build out in rural areas with the balance of the funds coming from the federal funding as proposed in several of the bills now before congress.
4) The private companies would also contribute existing telecommunications and power line towers, back-haul, and right-of-way access.
5) The network would then be available, on a secondary basis as follows:
    a. Power companies would use the network to meet their SmartGrid needs
        i. They could then resell broadband services to their rural customers for Internet access
    b. Telecommunications companies would also be able to make use of and resell wireless broadband services to their customers.
    c. Health Care and educations organizations would be able to make use of the network for their own use at favorable broadband rates.
6) The on-going cost of operating the network would be funded by a combination of the private and public safety entities that would make use of the network.

This type of private/public partnership would provide the state with almost 100% of the population with access to broadband services for their businesses, homes, schools, and other locations where broadband services are currently not available. Public Safety would have full use of the network during major disasters but at all other times the network would be shared by all of the contributing parties.

It should be noted that during a major disaster or incident that required Public Safety pre-emption of the broadband network this pre-emption would only occur within the immediate are of the disaster while other areas of the state would remain unaffected and therefore broadband services would be available.

This type of program will provide the state with broadband services to its rural population at affordable prices, AND will provide broadband services in these areas faster than any plan that has, so far, been presented by the federal or state Government.

An Analysis of State of Kentucky and Broadband Services

Senator: Mitch McConnell

State Statistics:

Total Population: 4,314,113 (2009 Est)

Broadband usage in Kentucky (NTIA 2007 statistics):

Total Households:	1,749,000	
Total with Internet access:	960,000	54.86%
Total with dial-up access:	253,000	14.44%
Total with broadband access:	700,000	40.02%
Total with anywhere access:	1,166,000	66.67%

According to the ITU Report (for all of United States)

Internet users in 2010	239,893,600	77.3%
Broadband users	85,287,100	

Conclusions:
In Kentucky, 253,000 households have only slow-speed dial-up access available.
In Kentucky, 1,049,000 households have no access to broadband services.

Broadband for Kentucky:

The recent stimulus funds made available by NTIA and IUS did not materially increase the broadband penetration rate in Kentucky.

What is needed in order to provide broadband access to most of the citizens of Kentucky are private/public partnerships. Commercial wired and wireless operators do not build facilities where the population per square mile is low. There is no return on investment for these companies to cover these rural areas in any state.

Coverage of most of the population of Kentucky *CAN* be provided if there are public/private partnerships.

IF the 700-MHz D Block is reallocated to Public Safety *THEN* there will be sufficient spectrum to enable private/public partnerships in the rural areas of Kentucky and broadband services can be made available.

A Workable Business Model:

One business model that has been proposed for other states where the rural population does not have access to broadband services is as follows:

1) The Public Safety Governance organization (the license holder), or the State of Kentucky, enters into a public/private partnerships with interested parties to build out the 700-MHz Public Safety broadband network in the district.
2) The private companies involved could include private telecommunications companies, local power utilities, health care and educational organizations.
3) The private companies would help fund the cost of the network build-out with the balance of the funds coming from Federal funding as proposed in Senate Bill 911 which was passed by committee 24/4 (a bipartisan vote) and which is now ready to be introduced in the full Senate.
4) The private companies would also contribute right-of-ways, existing telecommunications and power line towers, backhaul, and right-of-way access, thus making the build-out of this shared wireless broadband system more attractive and feasible for both the private and public entities.
5) The network would then be available, on a secondary basis as follows
    a. Power companies would use the network to meet their SmartGrid needs.
        i. They could then resell broadband services to their rural customers for Internet access.
    b. Telecommunications companies would also be able to make use of and resell wireless broadband services to their customers.
    c. Health care and educational organizations would be able to make use of the network for their own use at favorable broadband rates.
6) The ongoing cost of operating the network would be funded by a combination of the private and Public Safety entities that would make use of the network.

One set of potential private partners is listed below. Many of these companies are non-profit coops, and are members of the National Rural Telecommunications Cooperative. Many of them are power companies and the NRTC, on behalf of its members, has expressed an interest in working with Public Safety in the type of public/private partnerships described above:

Big Rivers Electric Corporation
Blue Grass Energy Cooperative Corporation
Clark Energy Cooperative, Inc.
Cumberland Valley Electric
East Kentucky Power Cooperative
Farmers Rural Electric Cooperative
Fleming Mason Energy
Foothills Rural Telephone Cooperative Corporation
Fox Creek R.E.C.C.
Gearheart Communications / dba Inter Mountain Cable, Inc.
Grayson Rural Electric Cooperative Corp
Green River Electric Corporation
Harrison County R.E.C.C.
Henderson Union RECC
Hickman-Fulton Counties Rural Electric Cooperative Corporation
Inter-County Energy Cooperative
Jackson Energy Cooperative
Jackson Purchase Energy
Kenergy
Kentucky Association of Electric Cooperatives
Licking Valley Rural Electric Cooperative Corporation
Logan Telephone Cooperative
Meade County Rural Electric Cooperative

Mountain Rural Telephone Cooperative Corporation
Nolin Rural Electric Cooperative Corporation
Owen Electric Cooperative, Inc.
Pennyrile Rural Electric Cooperative Corporation
Peoples Rural Telephone Cooperative
Salt River Electric Cooperative Corporation
Shelby Rural Electric Cooperative Corporation
South Central Rural Telephone Co.
South Kentucky Rural Electric Cooperative Corporation
SouthEast Telephone, Inc.
Taylor County Rural Electric Cooperative Corporation
Three Oaks Marketing and Development
Warren Rural Electric Cooperative Corporation
West Kentucky RECC
West Kentucky and Tennessee Telecommunications Cooperative

This type of private/public partnership would provide almost 100% of the population of Kentucky with access to broadband services for their businesses, homes, schools, and other locations where broadband services are currently not available today. Public Safety would have full use of the network during major disasters but at all other times the network would be shared by all of the contributing parties.

This type of program will provide the State of Kentucky and other states with broadband services to their rural populations at affordable prices *AND* will provide broadband services in these areas faster than any plan that has, so far, been presented by the Federal or State Governments.

Results in Near 100% 9opulation Coverage and Higher Data Speeds

One business model that has been proposed for other states where the rural population does not have access to broadband services is as follows:

1) The Public Safety Governance organization (the license holder), enters into a public/private partnerships with interested parties to build-out the 700-MHz Public Safety broadband network in the state.
2) The private companies involved could include private telecommunications companies, local power utilities, health care and educational organizations.
3) The private companies would help fund the cost of the network build out in rural areas with the balance of the funds coming from the federal funding as proposed in several of the bills now before congress.
4) The private companies would also contribute existing telecommunications and power line towers, back-haul, and right-of-way access.
5) The network would then be available, on a secondary basis as follows:
    a. Power companies would use the network to meet their SmartGrid needs
        i. They could then resell broadband services to their rural customers for Internet access
    b. Telecommunications companies would also be able to make use of and resell wireless broadband services to their customers.
    c. Health Care and educations organizations would be able to make use of the network for their own use at favorable broadband rates.
6) The on-going cost of operating the network would be funded by a combination of the private and public safety entities that would make use of the network.

This type of private/public partnership would provide the state with almost 100% of the population with access to broadband services for their businesses, homes, schools, and other locations where broadband services are currently not available. Public Safety would have full use of the network during major disasters but at all other times the network would be shared by all of the contributing parties.
It should be noted that during a major disaster or incident that required Public Safety pre-emption of the broadband network this pre-emption would only occur within the immediate are of the disaster while other areas of the state would remain unaffected and therefore broadband services would be available.

This type of program will provide the state with broadband services to its rural population at affordable prices, AND will provide broadband services in these areas faster than any plan that has, so far, been presented by the federal or state Government.

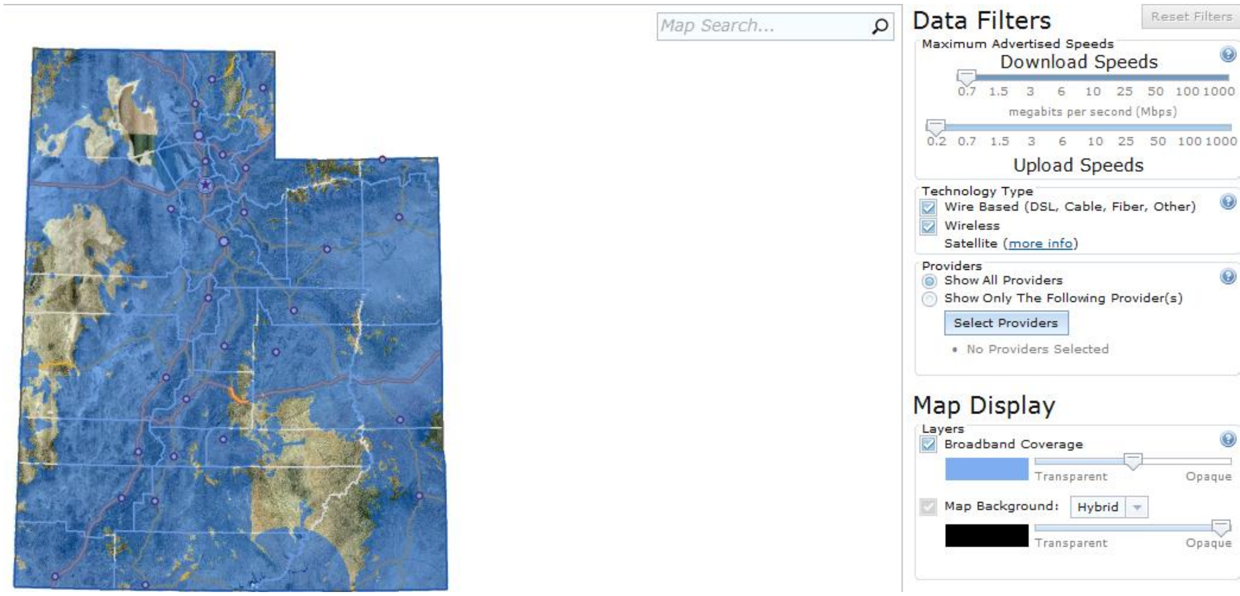
Current map of broadband availability:



The recent stimulus funds made available by NITA and IUS did not materially increase the broadband penetration rate in Utah. Private providers will not build either wired or wireless broadband infrastructure in rural areas with low density populations. They simply cannot afford to do so. What is needed in order to provide broadband access to most of the citizens of Utah are private/public partnerships.

Coverage of most of the population of Utah CAN be provided if there are public/private partnerships.

IF the 700 MHz D block is re-allocated to public safety THEN there will be sufficient spectrum to permit private/public partnerships in the rural areas of Kentucky and broadband services can be made available.

A Workable Business Model:

One business model that has been proposed for other states where the rural population does not have access to broadband services is as follows:

1) The Public Safety Governance organization (the license holder), and/or the State of Utah, enters into a public/private partnerships with interested parties to build out the 700-MHz Public Safety broadband network in the district.
2) The private companies involved could include private telecommunications companies, local power utilities, health care and educational organizations.
3) The private companies would help fund the cost of the network build-out with the balance of the funds coming from Federal funding as proposed in Senate Bill 911 which was passed by committee 24/4 (a bipartisan vote), and which is now ready to be introduced in the full Senate.
4) The private companies would also contribute right-of-ways, existing telecommunications and power line towers, backhaul, and right-of-way access, thus making the build-out of this shared wireless broadband system more attractive and feasible for both the private and public entities.

5) The network would then be available, on a secondary basis as follows:
    a. Power companies would use the network to meet their SmartGrid needs.
        i. They could then resell broadband services to their rural customers for Internet access.
    b. Telecommunications companies would also be able to make use of and resell wireless broadband services to their customers.
    c. Health care and educational organizations would be able to make use of the network for their own use at favorable broadband rates.
6) The ongoing cost of operating the network would be funded by a combination of the private and Public Safety entities that would make use of the network.

One set of potential private partners is listed below, many of these companies are non-profit coops, and are members of the National Rural Telecommunications Cooperative (NRTC) .Many of them are power companies and the NRTC, on behalf of its members has expressed an interest in working with public safety in the type of public/private partnerships described above:

Utah Telcos
Beehive Telephone, St. George
Central Utah Telephone, Fairview
Emery Telephone, Orangeville
South Central Utah Telephone, Escalante
Uintah Basin Telecommunications Association, Roosevelt

Utah Electrics
Dixie Escalante Rural Electric Association (REA), Beryl
Garkane Energy Coop, Loa
Moon Lake Electric Association (EA), Roosevelt
Utah REA, South Jordan

This type of private/public partnership would provide almost 100% of the population of the State of Utah with access to broadband services for their businesses, homes, schools, and other locations where broadband services are currently not available today. Public Safety would have full use of the network during major disasters but at all other times the network would be shared by all of the contributing parties. It should be noted that with broadband technology, built in a cellular network configuration only the area directly affected by the disaster would have limited or not access to broadband services, all other areas of the statewide system would remain available to secondary usage.

This type of program will provide the State of Utah and other states with broadband services to their rural populations at affordable prices *AND* will provide broadband services in these areas faster than any plan that has, so far, been presented by the Federal or State Governments.

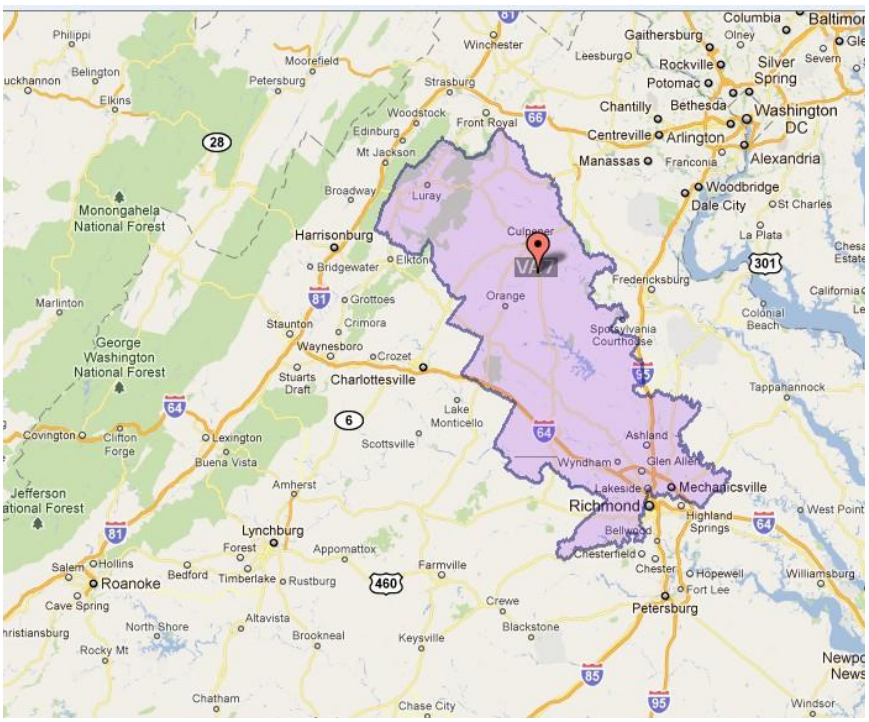
An Analysis of Virginia's 7th Congressional District

Representative: Majority Leader Eric Cantor

7th District of Virginia: Jurisdictions

Part of: Henrico, Richmond city, Chesterfield, Caroline, and Spotsylvania All of: Hanover, Goochland, Louisa, Madison, Orange, Culpeper, Rappahannock, and Page

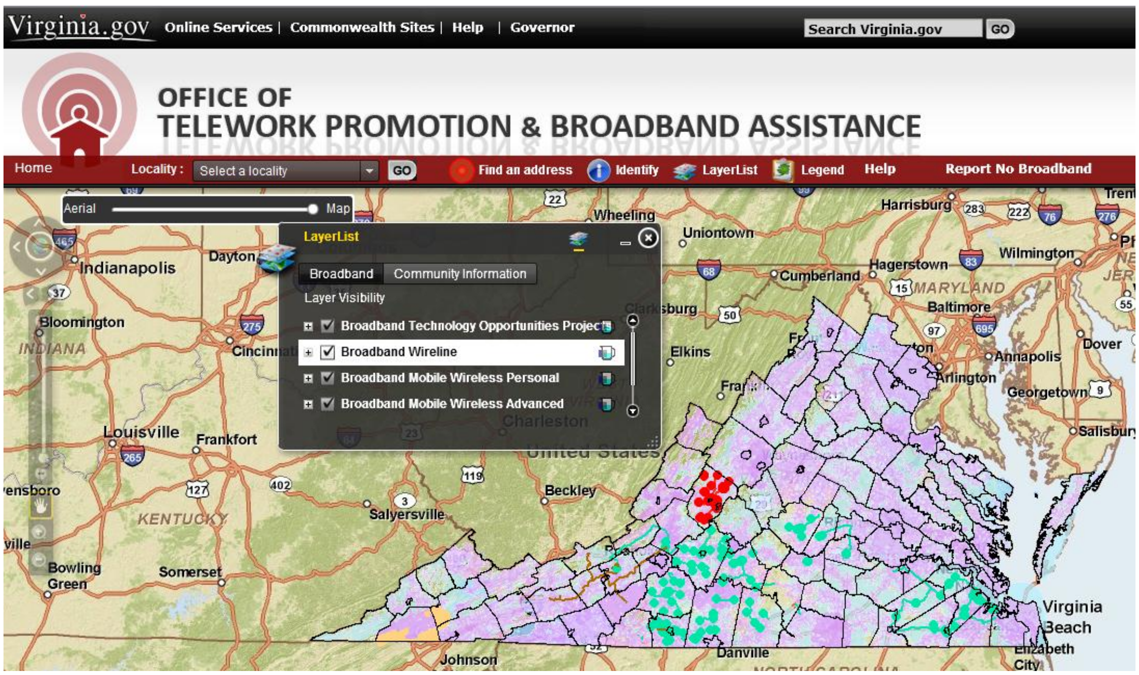


Population (2000)	643,499
Median income	[$](#)50,990
Ethnicity	79.1% White, 16.2% Black, 2.3% Asian, 2.0% Hispanic, 0.3% Native American, 0.2% other
Cook PVI	R+9

While no specific information appears to be available for the 7th District in Virginia, the statistics for broadband in rural Virginia are as follows:

Total State Population:	7,078,515
Urban Population:	5,169,955
Rural Population:	1,908,560
Percent of the State population with high speed access:	78.8 percent

The Governor's office for the State of Virginia has issued a series of maps depicting in which portions of the state broadband services are available. This first map shows that a significant portion of the State is already covered by broadband, however it should be noted that is map includes Broadband Wire line services (usually DSL or Cable with data speeds of between 1 and 3 Mbps, as well as two forms of mobile broadband coverage. The maps below show the State's broadband status for both what is called Broadband Mobile Wireless Personal and Broadband Mobile Wireless Advanced.



As can be seen from these two maps the State of Virginia and including the 7th district has wireless broadband coverage at the lower data rate (Broadband Wireless Personal) but when reviewing the map for Mobile Wireless Advanced services, (4G or LTE services) the State remains basically uncovered.

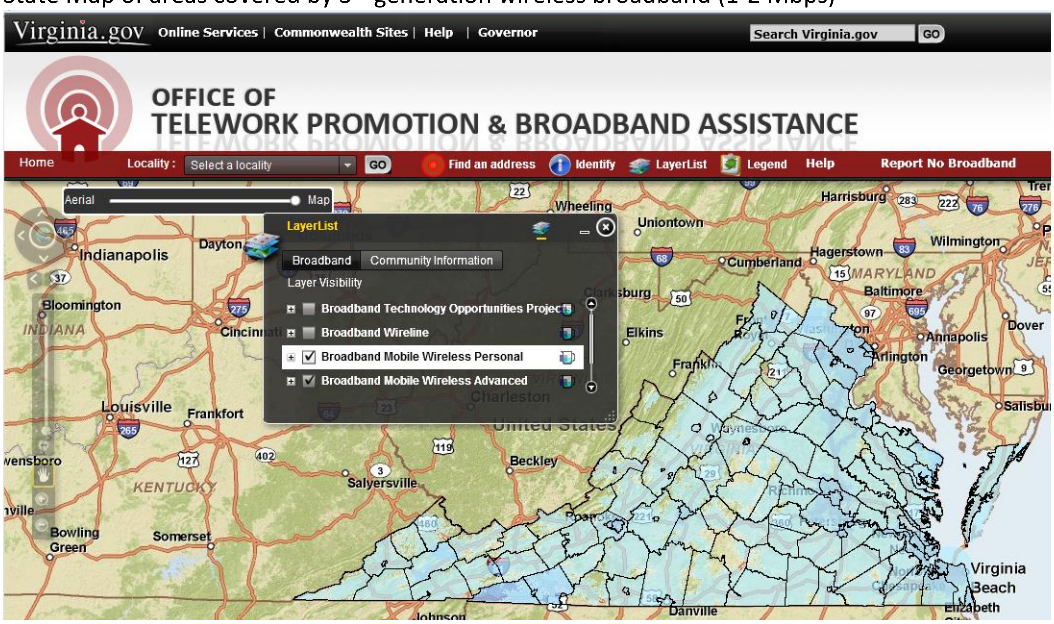
The expansion of 4G or LTE high-speed broadband wireless services will be slow to materialize because of the large investment required by the commercial network operators. However, if the D block is re-allocated to public safety, in many rural areas of Virginia, including those within the 7th Congressional District, Public Safety will be able to team up with many potential private companies to jointly build out 4G broadband wireless.

These public/private partnerships would provide much faster deployment of 4th generation broadband wireless services in all of Virginia but especially in the rural areas. The public safety community (local jurisdictions) would enter into these partnerships which would permit the private companies to contribute funding, and existing cell sites and power lines as well as back-haul, and would result in a rapid build out of the entire State. In this manner the State of Virginia and including the 7th Congressional district would achieve near 100% broadband coverage within the next few years.

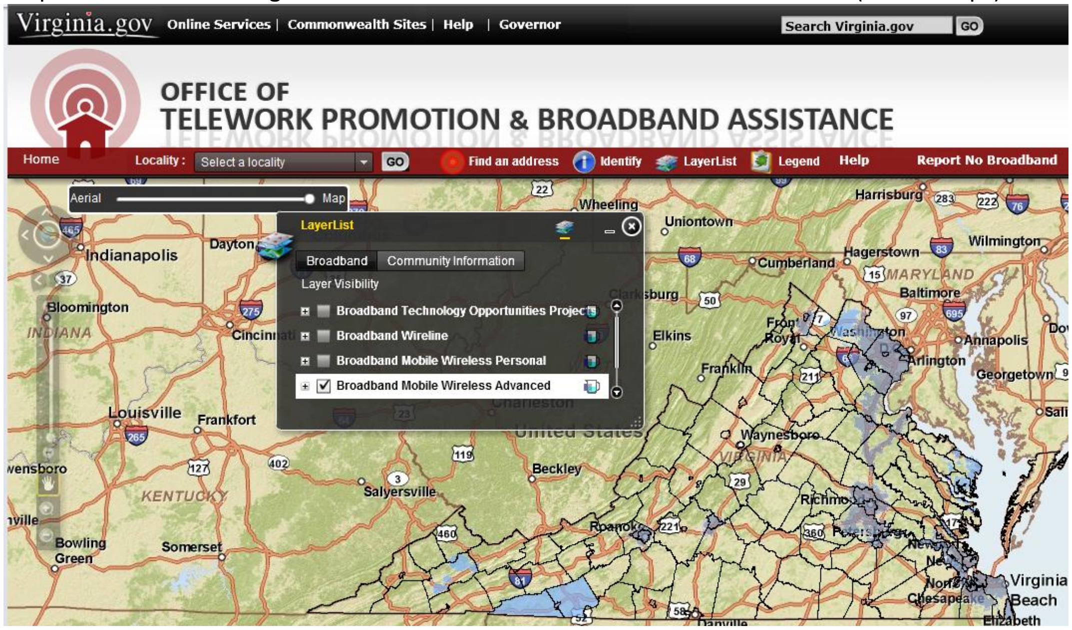
The business model could look something like this:

1) The Public Safety Governance organization (the license holder), or the State of Virginia, enters into a public/private partnership with interested parties to build out the 700 MHz Public Safety broadband network in district.
2) The private companies involved could include private telecommunications companies, local power utilities, health care and educational organizations.
3) The private companies would help fund the cost of the network build out with the balance of the funds coming from the Federal funding as proposed in several of the bills now before congress.
4) The private companies would also contribute rights of way, existing telecommunications and power line towers, back-haul, and right of way access.
5) The network would then be available, on a secondary basis as follows:
    a. Power companies would use the network to meet their SmartGrid needs
        i. They could then resell broadband services to their rural customers for Internet access
    b. Telecommunications companies would also be able to make use of and resale wireless broadband services to their customers.
    c. Health Care and educations organizations would be able to make use of the network for their own use at favorable broadband rates.
6) The on-going cost of operating the network would be funding by a combination of the private and public safety entities that would make use of the network.

State Map of areas covered by 3rd generation wireless broadband (1-2 Mbps)



Map of the State showing current 4th Generation Wireless Broadband Services (12-15 Mbps)



This type of private/public partnership would provide the 7th District of Virginia with almost 100% of the population with access to broadband services for their businesses, homes, schools, and other locations where broadband services are currently not available today. Public Safety would have full use of the network during major disasters but at all other times the network would be shared by all of the contributing parties.

During times of a major emergency only those secondary customers within the affected area would be have reduced access or no access to the wireless broadband network. Those outside of the affected area would still have full access the wireless broadband network on a secondary basis.

Conclusion:

These types of public/private partnerships, on a local level, are good for public safety, good for the private companies who will be working with the public safety community to build and operate this network and will provide faster broadband in the rural areas of the State, including the 7th Congressional district to those living in these rural areas.

As far as I know there is nothing planned with in the State or the 7th District which will provide broadband services to not only the first responder community but to private companies as well as the residents of the area in such a timely and affordable manner.

PHOENIX CENTER FOR ADVANCED LEGAL & ECONOMIC PUBLIC POLICY STUDIES

Re-Auction of the D Block: A Review of the Arguments

George S. Ford and Lawrence J. Spiwak*

May 24, 2011

Introduction

Last March, we released a POLICY BULLETIN entitled: *Public Safety or Commercial Use? A Cost/Benefit Framework for the D Block,*[1] in which we proposed a framework to assess the relative benefits of having the government either assign the D Block to public safety or re-auction the spectrum for commercial use. Each approach has its costs and its benefits. Our analysis indicated that the 10 MHz D Block provides $3.4 billion more in social benefits if assigned to public safety rather than to commercial use, even accounting for the expected auction revenues from that block. That is, the financial benefits of public safety assignment exceed any lost auction revenue from the D Block.

Notwithstanding, some policymakers remain committed to a re-auction attempt of the D Block for commercial use. Many proponents of a D Block re-auction focus exclusively on the potential auction revenues from the block.[2] Others appear to believe the auction will somehow fund the entire (or at least a good chunk of the) public safety network.[3] In these tough financial times, it is difficult to criticize anyone looking for revenues or cost savings.[4] However, it is essential to consider the full financial effects of the allocation options, not simply those implications favoring one option or another.

In this PERSPECTIVE, we present a more holistic view of the financial implications of a D Block re-auction. First, we present evidence suggesting that the claimed $3 billion in revenue from a D Block re-auction is too rosy an expectation.[5] Statistical analysis of historical auctions indicates that a 10 MHz block of spectrum in the 700 MHz band must be *unencumbered* to produce $3 billion in revenues.[6] Yet, the FCC's *National Broadband Plan* envisions a number of significant encumbrances on any re-auction of the D Block which have substantially reduced auction revenues in the past.[7] (In 2008, the D Block failed to secure a minimum bid at auction of $1.3 billion due to onerous encumbrances, creating the stalemate among lawmakers and policymakers we are faced with today over this block of spectrum.)

> ***... re-auction of the D Block will increase government spending on the public safety network and reduce future auction revenues by far more than the re-auction may generate in revenues.***

Second, the re-auction of the D Block will under no circumstances come close to fully funding a public safety network. A nationwide public safety network is expected to cost about $10 to $13 billion. Even if a re-auction of the D Block did bring in $3 billion of revenues, it offsets only about one quarter of the public safety network's cost. The D Block re-auction offers no other mechanism by which to generate funds for the remaining network construction and operating costs. To date, the only formal proposal put forth to fund the public safety network with auction revenue is a voluntary incentive auction for television broadcast spectrum.[8]

Finally, we discuss the potential broader adverse market effects of a D Block re-auction. The evidence indicates that the public safety community needs a full 20 MHz of spectrum.[9] If the D Block is assigned to commercial use, then an additional 10 MHz for public safety must be obtained from either future spectrum assignments or the capacity-equivalent thereof obtained via burdensome public safety encumbrances on commercial spectrum.[10] This alternate block of spectrum will not be contiguous to the Public Safety Broadband ("PSB") Block, which has the effect of increasing the deployment cost of the public safety network by an estimated $4 billion relative to the D Block assignment.[11]

… a 10 MHz block of spectrum in the 700 MHz band must be unencumbered to produce $3 billion in revenues. Yet, the FCC's National Broadband Plan envisions a number of significant encumbrances on any re-auction of the D Block …

A commercial assignment of the D Block also has the potential of frustrating the creation of contiguous blocks of spectrum for future auctions, thereby substantially reducing auction revenues. Moreover, filling the public safety spectrum shortage with public safety obligations on all commercial providers could substantially reduce future auction revenues.

In all, a plausible case can be made that the re-auction of the D Block will increase government spending on the public safety network and reduce future auction revenues by far more than the re-auction may generate in revenues. Even under the favorable scenarios (e.g., $3 billion in revenues), the re-auction of the D Block does not appear to pass a cost-benefit test.

Revenues from the D Block are Likely to be Relatively Small

The D Block and the PSB Block are two contiguous 10 MHz blocks in the 700 MHz band. In 2008, the Commission attempted to auction the D Block to create a mandated public-private partnership for a public safety network. Since the D Block is contiguous to the 10 MHz PSB Block, the agency hoped that the partnership would permit some commercial use of the PSB Block and provide additional capacity for public safety professionals on the D Block when needed. As we all know, the effort was an unmitigated failure, effectively leaving fallow both blocks—a condition that persists today.[12]

Despite the D Block bust, the *National Broadband Plan* proposes to try again. Recognizing the past failure, the Commission hopes to "overcome past challenges by encouraging, though not requiring, incentive-based partnerships to ensure success."[13] In other words, the Commission intends to assign the D Block to commercial use, leaving the public safety community to make its way with its 10 MHz PSB Block, an amount that appears to be insufficient for a modern, interoperable public safety network.[14]

Some favor the agency's plan; others oppose it. Support for the re-auction of the D Block is based largely on its potential to generate auction revenue, which will be used to support unprecedented levels of federal deficit spending.[15] By government estimates, the D Block would generate about $3 billion in auction revenues.[16]

Based on an econometric analysis of the more recent spectrum auctions in the United States, if the FCC auctioned the D Block on a truly unencumbered basis, then we could expect the auction to generate revenues in the range $1.3 to $3.3 billion.[17] However, the re-auction of the D Block is not unencumbered. The Commission has made clear that it intends to impose costly requirements on any re-auction of the D Block.

While the agency hopes for a "voluntary"[18] public-private partnership, it nevertheless hedges, advancing a set of rules by which the D Block will be auctioned. These rules include the following:

- D Block licensee(s) must use a nationally standardized air interface [to] ensure that the D block will be technically capable of supporting roaming and priority access by public safety users of the neighboring public safety broadband block;
- D Block licensee(s) are required to provide such roaming and priority access to public safety users;
- D Block licensee(s) must develop and offer devices that operate both on the D Block and the neighboring public safety broadband block; and
- [D Block licensee(s)] should be subject to commercially reasonable buildout requirements.[19]

Clearly, the *National Broadband Plan*'s proposal for re-auctioning the D Block includes a number of meaningful value-reducing encumbrances.[20]

As what is past can easily become prologue, it is sensible to look for guidance at the effects of similar requirements from the original failed auction. Fortunately, we have available a detailed report on the first failed auction from the agency's own Inspector General ("IG"), who conducted a careful and detailed investigation into the reasons underlying the failure of the first D Block auction. This report contains numerous interviews with many of the major industry players, and presents a devastating critique of the public-private partnership approach to the public safety network.[21] Many of the findings in the IG's Report remain relevant to the *National Broadband Plan*'s re-auction proposal, as we discuss below.

Roaming and Priority Access

Perhaps the biggest conflict for any public safety public/private partnership comes over the crucial and highly contentious issue of roaming and priority access. Under both the FCC's old and new proposed paradigm, the D Block licensee is "*required* to provide roaming and [] priority access" for public safety use.[22]

... the re-auction of the D Block will under no circumstances come close to fully funding a public safety network.

In the case of the original D Block auction, the IG found such access requirements to be a major impediment to the successful implementation of the D Block paradigm. Indeed, as the IG pointed out, public safety's mandatory prioritization meant that commercial users on the D Block would have been "subject to the very kinds of service interruptions—during periods of peak preemption—deemed unacceptable to public safety."[23] One industry executive described the plan as "ruthless preemption" that would lead to "a very costly network with diminished commercial value."[24]

Moreover, given the requirement to enter into roaming and access agreements, the parties are obligated to set compensation to the private operator for use of its spectrum. A likely approach is for the FCC to impose on commercial providers a mandatory obligation similar to that imposed in the agency's recent *Data Roaming Order*, where parties must reach "commercially reasonable" roaming agreements with public safety entities or deal with the Commission as arbiter.[25]

... filling the public safety spectrum shortage with public safety obligations on all commercial providers could substantially reduce future auction revenues.

The problem with such a paradigm, particularly in regards to public safety entities, is that the Commission has very little credibility with Wall Street as a neutral arbiter of disputes. Indeed, in the case of the original D Block auction, the IG found that private firms expressed a legitimate "fear that the FCC would have a tendency to support the perceived needs [of public safety… and, as such, the] assurance that the FCC would monitor the negotiations, require good faith, and be the final arbiter of disputes was small comfort" to any prospective bidder.[26] Obviously, such risk will continue reduce the value of the D Block at any re-auction.

Increased Cost of Deployment

A network suitable for public safety also requires both higher technical standards and a larger footprint than does a strictly commercial network. And, logically, with such increased requirements comes higher network deployment costs, and, in turn, with higher deployment costs comes a lower auction value for the spectrum.[27] Former FCC Chairman Reed Hundt, who was serving as the President of potential D Block bidder Frontline Communications, conceded "the costs necessary to reach only a few additional users would entail a vastly disproportionate additional cost."[28] Likewise, Verizon testified that the buildout requirements were too "costly"[29] and Qualcomm testified that the buildout requirements were "too onerous", going so far as to note that these requirements were "far more expensive than any of the current [commercial] networks."[30]

The *National Broadband Plan's* re-auction proposal does not fully alleviate these cost concerns. The new D Block licensee would be required to take on cost-increasing mandates including: (1) the use of a Commission-selected air interface; (2) the mandate to develop and offer devices that operate both on the D Block and the PSB Block; and (3) the requirement to buildout the network on the agency's timetable.[31] All of these requirements could increase deployment costs, thereby reducing the auction value of the D Block.

The Value of the Encumbered D Block

According the FCC's Inspector General, public safety encumbrances on quasi-commercial spectrum create "many layers of uncertainty and risk," and these problems "were responsible for potential bidders' decisions not to bid" on the public/private partnership promoted by the agency.[32] The *National Broadband Plan*'s proposal likewise creates "many layers of uncertainty and risk," and it is reasonable to expect a significant diminution in the value of the block to private-sector bidders, reducing auction revenues.

Public safety obligations of the first auction attempt reduced the value of the spectrum by 86%[33] and, as discussed above, the FCC's re-auction plan embraces similar encumbrances. Moreover, in light of recent Commission actions in the *Harbinger Order,*[34] and the pending merger of AT&T and T-Mobile, we believe there will be few established bidders for the D Block, either as a result of carrier choice or, more likely, by government mandated exclusion.[35] Fewer bidders typically implies less revenue.

As we concluded in our earlier paper, a re-auction of the D Block could produce less than $1 billion in revenue and is unlikely to exceed $2 billion in the best plausible scenario.[36] (We note, however, such predictions are necessarily speculative.)

Revenues from a New D Block Auction Will Not Fully Fund a Public Safety Network

As noted above, one alleged benefit of re-auctioning the D Block is the creation of revenues to help fund the public safety network. It appears that some policymakers believe these revenues will be sufficient to fully fund the public safety network. Nothing could be further from the truth.

The cost of constructing a public safety network is estimated to be about $10 to $13 billion.[37] In light of the numerous encumbrances, it is unlikely that the D Block will generate auction revenues anywhere near the claimed $3 billion. A more reasonable estimate is revenue in the $1 billion to $2 billion range. So, under the best of conditions, therefore, the re-auction offsets about one one-third of the costs. A more plausible case is one-tenth of the cost.

Plainly, a D Block re-auction will not pay for the public safety network. Indeed, it will cover only a small share of the costs under the best of conditions, and, as explained in the next section, may actually increase the cost of the network.

Broader Adverse Market Effects of a D Block Re-Auction

As noted above, evidence indicates that public safety needs 20 MHz of spectrum to construct a modern, interoperable LTE public safety network.[38] Re-auctioning the D Block, however, leaves the public safety community with only 10 MHz of spectrum (the PSB Block). If 20 MHz is indeed required for a fully-functioning public safety network, then, as we explained in POLICY BULLETIN NO. 26, there are two solutions to resolve this shortfall, neither of which favor the re-auction of the D Block.

One option is to give additional spectrum, say 10 MHz, to the public safety community in the future. This block, however, will not be contiguous to the PSB Block. As a consequence, the efficiencies of contiguous spectrum are lost. Adding a non-contiguous 10 MHz block to the PSB Block increases deployment costs for the public safety network by about $4 billion.[39]

Now, rather than reducing the public cost of the public safety network by an amount equal to auction revenues (as re-auction proponents hope), the re-auction plan increases the cost of the network by more than any offered estimate of auction revenues. The re-auction places a heavier burden on government finances than does a reassignment of the block to public safety. In essence, it could be argued that the re-auction proposal is founded on the logic that $3 billion in revenues (at best) is sufficient to justify $4 billion in additional network deployment costs (which must be funded by the government).

... the re-auction of the D Block will increase government spending on the public safety network and reduce future auction revenues by far more than the re-auction generates in revenues.

A second approach is to burden all commercial providers with public safety obligations. Indeed, this approach is already being contemplated by the Commission. In the *National Broadband Plan's* re-auction plan, the Commission intends to impose a requirement that "commercial mobile radio service providers … give public safety users the ability to roam on commercial networks in 700 MHz and potentially other bands."[40] Unlike in the earlier attempt to auction the D Block, the Commission now proposes to extend the "priority access on commercial networks" to *"all networks using the 700 MHz band and potentially other networks as well."*[41]

Thus, under the agency's purportedly new and improved plan, the value-killing obligations that sank the first D Block auction apply not just to the D Block but to *all* spectrum licenses, sabotaging the commercial value of spectrum and increasing compliance costs for firms. As such, the expectation should be that the D Block re-auction curbs future auction revenues, including the contemplated voluntary incentive auction to reclaim unused broadcast spectrum. The plan also reduces the value of spectrum auctioned in the past, though we do not expect the Commission to issue refunds (though perhaps they should).[42]

The voluntary spectrum incentive auctions proposed for broadcast spectrum could break the stalemate on this vitally important issue regarding robust … broadband communications for America's first responders.

Depending on the rules, which the agency suggests may be expansive, the lost auction revenues could accrue on virtually all spectrum auctioned in future periods. Adding these lost revenues to the attenuation in commercial value of previously auctioned spectrum would easily swamp the $1 to $2 billion in auction revenues expected from the D Block. If true, the re-auction option appears exceedingly short sighted.

Conclusion

Resistance to the assignment of the D Block to the public safety community—thereby providing these vital public servants the resources to build a modern mobile communications network—rests largely on the hope of significant revenues generated from the re-auction of the D Block for commercial uses. However, a re-auction of the D Block offers far less revenue potential than the government predicts. Given the FCC's proposed encumbrances, and other likely auction rules imposed by an aggressively regulatory agency, the auction revenues from the block are more likely to be about $1 billion—about one-third of the number bandied about by auction proponents.

Yet, regardless of whether or not revenues are $1 billion or $3 billion, the auction revenues do not come close to fully funding the public safety network, as some appear to believe it will, and the re-auction plan offers no other source of revenue for funding the network. The government is on the hook for funding the vast majority of the costs of the public safety network. As noted above, to date, the only credible proposal that could provide sufficient spectrum to alleviate the looming spectrum exhaust and provide significant auction revenue sufficient to cover the cost of building a public safely network and have money left over for deficit reduction is the notion of voluntary incentive auctions to repurpose unused broadcast spectrum.[43]

If the 10 MHz PSB Block falls short of satisfying public safety's spectrum requirements, as studies indicate it will, then the re-auction of the D Block actually increases the taxpayer's share of network deployment costs by far more than anyone's expectation of auction revenues. Also, the re-auction will cut substantially future auction revenues if the Commission imposes public safety encumbrances on all 700 MHz spectrum and other spectrum as well to cover the spectrum shortfall for public safety.

In all, the notion that the re-auction of the D Block is a net positive for the government's budget is exceedingly weak. A more likely consequence is that the re-auction increases deficit spending by adding costs to the public network and reducing future auction revenues.

If Congress is truly serious about raising money through commercial spectrum auctions, then it should encourage federal regulators in their efforts to find more spectrum, including the repurposing of television broadcast spectrum to more valued uses. The voluntary spectrum incentive auctions proposed for broadcast spectrum could break the stalemate on this vitally important issue regarding robust, reliable and resilient broadband communications for America's first responders.

PUBLIC SAFETY OR COMMERCIAL USE? A COST/BENEFIT FRAMEWORK FOR THE D BLOCK

Abstract: The issue of whether the government should assign the D Block of spectrum to public safety or auction the spectrum for commercial use requires an assessment of the relative benefits and costs of these two alternatives. We propose such a framework, and preliminary analysis suggests that the 10 MHz D Block plausibly provides at least $3.4 billion more in social benefits if assigned to public safety rather than to commercial use. Much of this difference is attributable to the unique opportunity to create a contiguous 20 MHz block of spectrum, and to the fact that this opportunity exists only for the public safety community. As for the lost auction revenue, we observe that the loss of auction revenues today is more than offset by the gain of higher auction revenues and lower public safety network deployment cost in the future. Thus, an auction of the D Block adds, rather than relieves, stress to the public budget. Finally, we estimate that if policymakers choose not to give public safety the D Block and instead opt to require service obligations on other 700 MHz spectrum that would permit the encroachment of public safety users during episodes of resource scarcity, then such encumbrances could materially diminish the auction value of any newly allocated 700 MHz spectrum by as much as 86%.

I. Introduction

As part of the reallocation of the spectrum made available by the digital television ("DTV") transition, the Federal Communications Commission boldly attempted to create, and fund, a nationwide interoperable public safety network. To make a very complicated story simple, as part of the DTV transition, Congress set aside approximately 10 MHz of the new spectrum for public safety use (commonly referred to as the "Public Safety Broadband" allocation or "PSB"). When the FCC set up its auctions for the DTV spectrum, it placed the PSB next to a contiguous 10 MHz of spectrum (the D Block) that was to be auctioned, so the theory went, to create a public/private partnership that could be used for both commercial and public safety purposes utilizing both the D Block and the PSB.[1] However, due to the public service obligations imposed on the D Block auction and the questionable logic of the scheme, the auction effort failed, an outcome of little surprise to anyone.[2] Today, three years after the failed auction, the debate about what should be done next about the D Block is fully engaged.[3]

Given the observed failure of the "public/private partnership" approach, the rapid rise in public safety capacity demands, and the unique benefits of combining the PSB and the D Block, the public safety community has requested that the Federal government forgo the auction of the D Block and directly assign it to public safety. This allocation would thus provide for a full 20 MHz of contiguous prime spectrum that could be used to construct a modern, interoperable nationwide public safety communications network.[4] The FCC to date has rejected this request, planning instead to auction the D Block on an unencumbered basis for commercial use (subject to technical capability for public safety broadband use),[5] although the agency has granted some waivers to begin operations in the PSB.[6] In the FCC's view, any shortfall in capacity on the

(Footnote Continued….)

public safety network can be resolved by roaming agreements with commercial carriers.[7] And, of course, an auction brings with it the potential to enrich the Treasury with much needed revenues.[8]

Interestingly, the White House has rejected the FCC's proposal and has sided with the public safety community, explicitly calling for the reallocation of the full 20 MHz of contiguous spectrum to build a modern, interoperable nationwide public safety network.[9] Such a position is consistent with the "Public Safety Spectrum and Wireless Innovation Act" recently introduced by Commerce Committee Chairman Senator Jay Rockefeller (D-WV), which would also give public safety the entire 20 MHz of the D Block and PSB.[10] This plan has received wide bi-partisan support,[11] although the FCC was reportedly opposed to it.[12] Other policymakers from both political parties, however, have views more aligned with those of the Commission,

and are calling for the prompt auction of the D Block for commercial purposes.[13] This intra-governmental quibbling proceeds unabated as the public safety community waits to build a modern communications network.

Resolution to the D Block issue is a complex problem. Here, we present an economically-valid framework—heretofore absent from the debate—within which we can evaluate the cost and benefits of the relevant alternatives. While we cannot claim to answer every question relevant to the allocation decision and some of our estimates are necessarily speculative (e.g., what is the social value of public safety?), our analysis suggests that the assignment of the D Block to public safety is advised, with a net benefit of $3.4 billion dollars even when we pointedly ignore the benefits of the additional spectrum for the provision of public safety. The cost-benefit calculus depends largely on the benefits arising from the technical and economic advantages of contiguous spectrum and the relatively small impacts of a temporary, incremental increase of 10 MHz of spectrum on market outcomes. While more research on this topic is warranted, we hope future contributions will adhere to an explicit, rational framework for analysis.

II. A Decision Framework

A sensible decision framework begins by recognizing there are costs and benefits to all actions. If alternatives are mutually exclusive, as is the assignment of a *particular* 10 MHz block of spectrum, then assignment to one party excludes assignment to any other. In other words, assignment has an opportunity cost, and the proper accounting of such costs and their offsetting benefits is critical to rational decision making. The goal of public policy is to maximize economic well-being by choosing the option with the highest net value to the people of the United States.

A review of the D Block debate suggests the following characterization. Today, there is 10 MHz of spectrum that can be allocated either for public safety or for commercial purposes.[14] This D Block is contiguous to the 10 MHz PSB block already dedicated to public safety, permitting a unique opportunity for a public safety network of 20 MHz using contiguous

[13] *See, e.g.*, Sara Jerome, *Blackburn Supporting D Block Auction,* THE HILL (January 24, 2011); Sara Jerome, *GOP Torn Between Homeland Security, Fiscal Restraint in Public Safety Fight,* THE HILL (January 26, 2011) (available at: http://thehill.com/blogs/hillicon-valley/technology/140475-gop-torn-between-homeland-security-fiscal-restraint-in-public-safety-fight); Rep. Henry Waxman, *Emergency System Needs Upgrade,* ROLL CALL (July 8, 2010)(available at: http://www.rollcall.com/features/Technology_Telecommunications/tandt/-48166-1.html).

[14] We ignore other alternatives not part of the present debate.

spectrum.[15] In the relatively near future, according to the FCC and the Obama Administration, there will be much more spectrum available. The Federal government is in the process of adding an additional 500 MHz of spectrum for commercial use, with 300 MHz of that spectrum intended to be online by 2015.[16] The need for additional spectrum for the commercial sector has been established, and the evidence indicates that public safety's current and expected needs exceed 10 MHz.[17] Thus, we assume there will be another 10 MHz that must be allocated to whichever party does not receive the current allocation. However, this new spectrum will not be contiguous to the PSB, and the D Block will not be contiguous to this new spectrum. Additionally, this future 10 MHz block allocation is assumed to be part of a contiguous block, an option likely to become available as the government reassigns 500 MHz of spectrum to commercial uses. The issue, therefore, is about the timing of benefits and costs, with one type accruing now and the other later.

Given this specification, there are two relevant options to consider in a cost-benefit tradeoff. In the first option, the D Block spectrum, which is contiguous to the PSB 10 MHz already assigned to public safety, is allocated to the public safety community, which precludes its auction now to the commercial sector. This choice permits the benefits and costs derived from public safety's use of the spectrum to accrue now, while postponing the benefits and costs from commercial use of this additional 10 MHz of spectrum into the future. That is, allocating the

---

15 *See, e.g.*, Public Safety Alliance, *House of Cards: FCC's Capacity White Paper Built on Assumptions and Conjecture* (July 2, 2010) at 3 ("Since the D-Block spectrum is adjacent to the public safety broadband allocation, it is uniquely positioned to provide the needed additional capacity throughput for a public safety agency's entire coverage area including the cell edge where throughput decreases significantly. Any alternative spectrum offered in other bands will be less efficient. Additional components would be required which would increase the cost and reduce performance of broadband devices. Non-adjacent spectrum blocks of the same size as the D Block will not provide as much throughput capacity, since greater efficiency is achieved through spectrum aggregation.").

16 *National Broadband Plan* at XII ("Make 500 megahertz of spectrum newly available for broadband within 10 years, of which 300 megahertz should be made available for mobile use within five years."); Remarks by Lawrence H. Summers, *Technical Opportunities, Job Creation and Economic Growth* (June 28, 2010) (available at: http://www.whitehouse.gov/administration/eop/nec/speeches/technological-opportunities-job-creation-economic-growth); *Plan and Timetable to Make Available 500 Megahertz of Spectrum for Wireless Broadband*, Department of Commerce (October 2010)(available at: http://www.ntia.doc.gov/reports/2010/TenYearPlan_11152010.pdf).

17 Bill Schrier, Chief Technology Officer, City of Seattle, *Public Safety, Government, Wireless and Spectrum*, National League of Cities (May 27, 2010) (""[M]ost urban areas will rapidly outgrow the capacity of the 10 MHz allocated by the FCC for the public safety networks."); Andrew Seybold, *Response to Roberson and Associates, LLC White Paper entitled "Technical Analysis of the Proposed 700 MHz D-Block Auction, dated August 23, 2010, contracted for by T-Mobile USA, Inc.",* (September 10, 2010) at 5 (available at: http://andrewseybold.com/wp-content/uploads/2010/09/ResponseT-MobileWP09-10-10FNL.pdf) ("Data usage has grown on commercial networks in the order of 5000% in only the past three years. Demand will follow the same curve as the commercial broadband sector as new applications and devices become available for Public Safety…").

contiguous D Block to public safety only *postpones* the allocation of an additional 10 MHz for commercial purposes (which the "new" block comes from the 500 MHz of spectrum promised by the FCC and the Obama Administration). In the second option, the D Block is auctioned for commercial purposes now, precluding its assignment for public safety purposes. In this case, the incremental benefits and costs from commercial use accrue now, but the benefits and costs of public safety's use are postponed. Framed in this way, the relevant issue is not whether the 10 MHz is used for public safety or used for commercial use, but rather *when* and *which* 10 MHz is put to use in both, and how the size and timing of benefits compare between these two alternatives.

More formally, let B_s^t represent the incremental benefits and C_s^t the incremental cost of an additional 10 MHz of spectrum assigned to sector s at time t, where s has values P for public safety and A for commercial application, and where t is 0 for the present and 1 for the future. The incremental net value of public safety assignment of the D Block today is $V_P^0 = B_P^0 - C_P^0$ today, and $V_P^1 = B_P^1 - C_P^1$ in the future. In the same way, we have net benefit V_A^0 if the 10 MHz is auctioned for commercial purposes today, and V_A^1 given future allocation. Applying the constraint that each party receives a 10 MHz block, then the best policy decision is simply to take the highest value of the two sums $V_P^0 + V_A^1$ (i.e., public safety now, auction later) and $V_A^0 + V_P^1$ (i.e., auction now, public safety later).[18] The D Block spectrum should be given to public safety if $V_P^0 + V_A^1 > V_A^0 + V_P^1$, or equivalently, $V_P^0 - V_P^1 > V_A^0 - V_A^1$. Notably, all the costs and benefits that enter into these valuations are incremental to the status quo. That is, costs and benefits are measured only for the additional 10 MHz allocation.[19]

Armed with this simple but useful framework, we can provide some meaningful commentary on this important issue and interpret some of the available evidence in a pertinent manner. In what follows, we evaluate some of the evidence and issues using the cost-benefit framework, and we believe this exercise is highly informative.

III. Assigning the D Block to Commercial Use

The total economic benefits of commercial use include profits and consumer surplus, where these benefits are only those added by the addition of 10 MHz of spectrum. As for profits, assuming there are a few relatively homogeneous bidders, the profits from the added spectrum

---

[18] We ignore the possibility of either party getting both allocations.

[19] The upper 10 MHz of the D Block is already allocated to public safety and a network will be built to use that spectrum. Those costs are not incremental to the D Block.

will be largely dissipated at auction.[20] Based on an econometric analysis of the more recent spectrum auctions in the U.S., if the FCC auctioned the D Block on a truly unencumbered basis, then we could expect the auction to generate revenues in the range \$1.3 to \$3.3 billion.[21] There are, however, many reasons to expect this range of potential revenues is too high, including the Commission's recent track record of trading off auction revenues for other goals.

First, as seen in the earlier attempt to auction the D Block, public service obligations levied on the commercial license holder substantially reduce the value of spectrum. Only one bid was received in that auction (\$472 million) and it was well below the minimum bid established by the Commission (\$1.3 billion). The public safety encumbrances, therefore, imposed costs of about \$0.8 to \$2.8 billion, as reflected in the low bid value.[22] Given the lack of any service rules for the re-auction of the D Block, it is unclear what public safety encumbrances will be placed on the spectrum. The *National Broadband Plan* proposes that the commercial use be "technically compatible with the public safety broadband services," so some constraints will be placed on a commercial winner.[23] If there is an auction, and in light of the current debate, then we suspect there will be significant political pressure to impose public safety obligations on the D Block.[24] Thus, the expected auction revenues should be reduced to account for some types of public service obligations. If these obligations are even half as burdensome as those in the original auction, then the reduction in auction revenue would still be a sizeable 40%.

Second, the Commission has imposed certain obligations on spectrum blocks set for auction. For example, the Commission imposed stringent open platform obligations in the C Block auction of the 700 MHz spectrum, with disastrous results. Indeed, the conditions placed on the C block reduced auction revenues by a whopping 32%, with little to no perceptible benefit.[25]

24 *See*, *e.g.*, *Whitepaper: Technical Analysis of the Proposed 700 MHz D-Block Action*, Prepared for T-Mobile by Roberson and Associates, Inc. (August 23, 2010) (available at: http://fjallfoss.fcc.gov/ecfs/comment/view?id=6015952735), arguing that the D Block can effectively be shared under a public safety obligation. We provide no comment on the legitimacy of the analysis, but simply note that its relevance presumes the FCC will impose a public safety obligation on the D Block and that such obligations reduce expected auction revenues.

25 *Using Auction Results, supra* n. 20.

Although the Commission did not go as far when it promulgated its recent *Open Internet Order*, the Commission did impose some obligations on wireless network operators and, equally important, threatened to extend the full C Block conditions to other commercial licensees if circumstances warrant.[26] Accordingly, it is not unreasonable to expect that the Commission could extend obligations to the D Block, including C Block-type obligations, and, as such, we expect the auction revenues for the D Block to be lower than a naïve model would predict.

Third, given the Commission's recent *Harbinger* decision[27] and concerns expressed in its *14th CRMS Report* about industry concentration[28], it is also not unreasonable to assume that the Commission may exclude some bidders from the auction.[29] A reduction in the number of bidders, particularly if these potential bidders are large firms, is likely to reduce the expected auction revenue (ceteris paribus).[30]

Finally, the economic health of the country has deteriorated since the bidding in Auction 73. Thus, the D Block auction should not be expected to produce as much revenue as the earlier auctions. Coleman Bazelon estimates that the economic crisis will reduce the expected value of spectrum by approximately 20%.[31]

Spiwak, *The Broadband Credibility Gap,* PHOENIX CENTER POLICY PAPER NO. 40 (June 2010) (available at: http://www.phoenix-center.org/pcpp/PCPP40Final.pdf), *and forthcoming in* 19 COMMLAW CONSPECTUS (2011).

29 *C.f.,* Public Knowledge, "Spectrum Reform" ("The best method for ensuring that the spectrum is not simply bought by incumbent broadband providers is by limiting their eligibility to bid — either through a flat prohibition or spectrum caps.")(available at: http://www.publicknowledge.org/issues/spectrum-reform); Gregory Rose and Mark Lloyd, *The Failure of FCC Spectrum Auctions,* Center for American Progress (May 2006).

30 Auction theory indicates that a reduction in the number of bidders will reduce auction prices in an ascending, second-price auction. *See, e.g.,* L. Phlips, THE ECONOMICS OF IMPERFECT INFORMATION (1988), Ch. 4. Accordingly, a cynical interpretation of the debate might be that the D Block presents an opportunity for some industry participants to buy spectrum at reduced prices due to the likelihood the present Commission will exclude some bidders, and in doing so establish precedent for such exclusions in future auctions.

31 C. Bazelon, *The Need for Additional Spectrum for Wireless Broadband: The Economic Benefits and Costs of Reallocations*, The Brattle Group (October 2009) (available at: http://www.brattle.com/_documents/uploadlibrary/upload809.pdf).

Given these four factors, we expect the auction revenue from the D Block to be considerably less than the estimated range based on prior auctions ($1.3 to 3.3 billion). An auction of the D Block, depending on the rules, could produce less than $1 billion in revenue, and we suspect this low revenue amount is plausible given the current regulatory climate. We suspect auction revenue is unlikely to exceed $2 billion in the best *plausible* scenario but, again, such predictions are necessarily speculative.

Factors Reducing Auction Value of the D Block

1. Public Safety Obligations
2. Other Obligations, such as Open Internet/Platform Obligations
3. Excluded Bidders
4. Economic Crisis

As for consumer surplus additions, this relatively small addition of spectrum to the commercial sector (currently licensed 572 MHz by the Commission's count) is unlikely to be a game changer.[32] The consumer surplus gains from commercial assignment are limited to what little competitive effects may arise from the added spectrum. To evaluate this issue, we adopt a common, widely-used model of price formation familiar from previous analyses in telecommunications. Assuming Cournot Competition in Quantities, unit elasticity of demand, and a Hirschman-Herfindahl Index ("HHI") of 2500, we estimate the addition of 10 MHz of spectrum will reduce prices by about 0.6%.[33] Given a total market size of $160 billion, consumer

[32] *OBI Technical Paper No. 6*, p. 15 ("547 MHz, in total, is currently licensed under flexible use rules, which allows for mobile broadband and voice services").

[33] Price is defined as $P = cN/(N - 1)$, where c is marginal cost and N is the number of firms, taken to be the numbers-equivalent of the HHI (=1/HHI). Based on recent estimates, we assume an HHI of 2,500 producing an N of 4. *See 14th CMRS Report*, *supra* n. 27, at 51 (2,848) and Table 41 (2,200). Assuming 547 MHz of spectrum available, the addition of 10 MHz of spectrum is treated as the equivalent of adding 0.07 firms, resulting in a price cut of 0.6%. *See, e.g.*, J. Sutton, *Sunk Costs and Market Structure* (1995), Ch. 3; J.B. Duvall and G.S. Ford, *Changing Industry Structure: The Economics of Entry and Price Competition*, PHOENIX CENTER POLICY PAPER NO. 10 (April 2001) (available at: http://www.phoenix-center.org/pcpp/PCPP10Final.pdf) *and reprinted in* 7 TELECOMMUNICATIONS & SPACE LAW JOURNAL 11 (2001).

surplus gains (net of transfers) from this price cut are then about $600 million, annually.[34] While other models of price formation would yield different results, the Cournot approach used here is familiar, plausible, and implementable using relatively little information.

Another piece of the valuation puzzle arises from the fact that the future 10 MHz of spectrum could be part of a contiguous block. Turning again to the econometric analysis of previous auctions, the auction revenue from a contiguous 10 MHz block is expected to bring a premium of $2 to $6 billion (other things constant).[35] We assume that a 10 MHz block auctioned to commercial use in the future will be contiguous and will have an auction premium of $4 billion (the mid-point of the range).

Turning to the question of value, we can use this analysis to get a rough approximation of $V_A^0 - V_A^1$. Assuming the auction revenues are $2 billion, consumer surplus gains are $0.6 billion annually, the contiguous block premium is $4 billion, and the difference between time 0 and 1 is five years, the value difference from delay of the auction of 10 MHz is about $0.6 billion (= 2B + 2.6B - 4B).[36]

IV. Assigning the D Block to Public Safety

Perhaps the most daunting, yet relevant, question regards the social benefits of "public safety." Such benefits are real but difficult to quantify and, absent immediate crisis, prone to be undervalued. If we faced another event like 9-11 or Hurricane Katrina, we believe the 20 MHz would be allocated to public safety immediately and the network fully funded in a week's time. Fortunately, we are not presently victims of such a crisis and, though the lack of crisis makes the spectrum allocation decision a more difficult one, this is a burden we welcome. For the moment, we choose to set aside the quantification of the benefits of an additional 10 MHz of spectrum for public safety, looking instead at the cost side of equation.

Spectrum is not homogeneous. Not only is the 700 MHz spectrum highly valuable because its technical properties are well-suited for mobile communications, including broadband

---

34 The change in consumer surplus under unitary elasticity is market size in terms of expenditures (about $160 billion in 2010) multiplied by the natural log of the ratio of the new price to the old price. For expenditure data, see *Wireless Industry Indices: Mid-Year 2010 Results*, CTIA (November 2010) (available at: http://files.ctia.org/pdf/CTIA__Survey_Midyear_2010_Graphics.pdf).

35 *Using Auction Results, supra* n. 20.

36 We assume a discount rate of 4.4%. The discount rate is the government recommended discount rate for social projects evaluated over a twenty-year window. *See* OMB Circular No. A-94, APPENDIX C (Revised December 2009) (http://www.whitehouse.gov/OMB/circulars/a094/a94_appx-c.html).

Internet services, but for the public safety community the D Block has added value because it is contiguous to the PSB, which is already allocated to the public safety community. A contiguous block of 20 MHz of spectrum is substantially more valuable than 20 MHz of non-adjacent spectrum. As noted above, a 10 MHz block of contiguous spectrum in the 700 MHz band is worth about $2 to $6 billion more than a non-contiguous block of the same size.

While this value differential is estimated based on commercial use, much of this premium is based on the lower cost of deploying network for contiguous spectrum, which would likewise apply to public safety. Evidence suggests that the cost of the public safety network using 20 MHz of spectrum is probably about $10 billion.[37] Andrew Seybold, a highly regarded wireless industry expert, suggests that expanding a 10 MHz public safety network to 20 MHz adds about 15% to 25% to network deployment costs.[38] By this standard, the incremental cost of the additional 10 MHz is about $1.5 to $2.5 billion.[39] Alternately, adding a non-contiguous block of 10 MHz of spectrum to the public safety network would cost about $5 to $7.5 billion in deployment costs.[40] Assignment of the D Block to public safety, therefore, is likely to reduce the cost of the public safety network by around $4 billion in network deployment costs alone. Operational costs are likely to be lower as well, perhaps adding billions more to the savings.

---

[37] White House, *supra* n. 9 (assigning $7 billion in construction costs); *Broadband Network Cost Model*, *supra* n. 7 ($6.3 billion for a 10 MHz network).

[38] A. Seybold, *Comments on the FCC White Paper: Federal Communications Commission Omnibus Broadband Initiative A Broadband Network Cost Model: A Basis for Public Funding Essential to Bringing Nationwide Interoperable Communications to America's First Responders*, Working Paper (April 26, 2010), p. 15 (available at: http://andrewseybold.com/wp-content/uploads/2010/04/Comments-FCCWP-Final-April-27-2010.pdf). The FCC study, *Broadband Network Cost Model*, *supra* n. 7, claims an additional 10 MHz of spectrum would substantially *increase* the cost of the public safety network, but we find the extreme assumptions of that analysis to be unreasonable and in violation of economic logic. Seybold, *supra* n. 38 also rejects the agency's argument ("The Commission seems to believe that there are only two choices for building out the public safety broadband network. The first choice is its option to essentially combine it with the commercial networks except for some of the radio equipment. The second is to provide a totally separate and standalone network. The FCC does not take into account that between these two extremes is a number of options that can and should be explored.").

[39] Expanding commercial networks is also costly. There is little reason to suspect that the cost of a commercial expansion to additional 10 MHz will be much different than for the public safety community. For example, it was announced that Verizon is expected to spend $4 billion in equipment alone to deploy LTE, which is about $180 million per MHz of 700 MHz spectrum. For 10 MHz, the cost would be about $1.8 billion. *Verizon Wireless Awards Alcatel-Lucent Contract Expected to be Worth US $4 Billion for Ongoing 3G Network Expansion and LTE Build out*, Alcatel-Lucent Press Release (Nov. 4, 2010) (available at: http://www.alcatel-lucent.com/wps/portal/!ut/p/kcxml/04_Sj9SPykssy0xPLMnMz0vM0Y_QjzKLd4x3tXDUL8h2VAQAURh_Yw!!?LMSG_CABINET=Docs_and_Resource_Ctr&LMSG_CONTENT_FILE=News_Releases_2010/News_Article_002258.xml).

[40] Seybold, *supra* n. 38 at p. 15.

Moreover, the cost to deploy the 700 MHz band is much lower than other bands (some estimates are 70% lower than other bands). Thus, depending on what additional spectrum is provided to the public safety community if they do not receive the current 10 MHz block, the ultimate deployment costs could be substantially higher (though this differential may also apply to the commercial licensee). We leave a more sophisticated assessment of such costs to others, and assume here that the cost difference is $4 billion.

While we have not addressed the benefits of public safety's use of the additional 10 MHz of spectrum, which could be quite large, we can see that the contiguous spectrum premium of $4 billion is itself sufficient to offset the value of commercial assignment of an additional 10 MHz ($0.6 billion). Let Z be the marginal benefits from enhanced public safety created by the combination of the D Block for public safety use. From our cost-benefit framework, the relevant decision criterion for assignment to public safety is

$$V_P^0 - V_P^1 > V_A^0 - V_A^1, \tag{1}$$

approximated here to be

$$Z + \$4 \text{ billion} > \$0.6 \text{ billion}, \tag{2}$$

which plainly holds, even without sizing Z (where $Z > 0$ and potentially is very large). Even if the 10 MHz provided zero benefit in terms of enhanced public safety, then assignment of the D Block to public safety produces $3.4 billion in additional social value over and above the commercial value of the same block. (Of course, this is a result of the constraints we imposed on the problem, i.e., 10MHz of spectrum would be provided to public safety one way or another.) We have also ignored the value of spectrum currently used for narrowband purposes by public safety that may be repurposed for commercial use as a result of migrating existing public safety capacity demands to the D Block and PSB.[41]

Notably, much of this value spread arises from the unique opportunity to create significant value by allocating a contiguous block of spectrum to public safety, and then doing so in the future for commercial use. This value is foregone by commercial allocation of the D Block today. While some may contest our estimates, it is necessary to account for the economic value arising from contiguous spectrum.

---

[41] For example, Section 205(3) of the Rockefeller Bill, *supra* n. 10, requires the Commission to conduct a report within five years of enactment that examines, among other things, to determine whether there is an "opportunity for return of any spectrum to the Commission for auction to commercial providers to provide revenue to the Treasury of the United States."

V. An Alternative: Public Safety Encumbrances on Commercial Networks

Thus far in this analysis, we have assumed that if the D Block is used for commercial services, then an additional, non-contiguous 10 MHz block will be assigned for public safety use in the future. A realistic alternative to this grant of additional spectrum for public safety is simply to impose encumbrances on other 700 MHz spectrum that permit the encroachment of public safety users during episodes of resource scarcity. Unfortunately, however, it was exactly this approach that produced such miserable results in the first D Block auction. There are many complex issues that must be resolved with any sort of sharing scheme of this type, and such resolutions can be very costly. As revealed in Auction 73, public safety encumbrances substantially reduce the value of spectrum. Auctions revenues from an unencumbered D Block would have been about $3.3 billion, whereas the only bid for the encumbered block was a paltry $472 million—a mere 14% of its revenue potential.

Consider, for the moment, that incentive auctions for broadcast spectrum, which have been proposed in the Rockefeller bill, permit the recovery and repurposing of 120 MHz of quality spectrum. One study estimates that the auction revenues from this spectrum would be $35 billion, with a net value of $33 billion after relocation of existing licensees.[42] Our earlier research suggests that these predicted auction revenues are plausible.[43] Applying public safety obligations on this spectrum, however, would materially diminish its value. From the failed D Block, we might conclude that public safety obligations would reduce the auction value of the 120 MHz of spectrum to as little as $5 billion (= 35 × 0.14), a loss in revenues of $30 billion or 86% of its potential. This calculation likely represents the upper boundary of lost auction revenues since it presumes the encumbrances apply equally to all 120 MHz. Alternately, at the other extreme, using the size of the D Block in proportion, the reduction in auction revenues would be more to the tune of $2.5 billion, which is still a sizeable amount and probably more than the sale price of the D Block in a present day auction.[44] Notably, both numbers are underestimates of the total value loss since they measure only the loss in private value from the spectrum. We have ignored in these calculations the higher cost and diminished value to the public safety community (and those they serve) due to the reduced functionality inherent to a sharing of networks purposed mainly for commercial use. The fact of the matter is that no

---

42 *See supra* n. 10.

43 We estimate a 10 MHz block could yield $3.3 billion in auction revenue. A total of 120 MHz of spectrum, in turn, would render about $40 billion. We note there are factors that could raise or lower auction revenues in the future such as encumbrances, market conditions, the number of bidders, and so forth.

44 A 10 MHz block is 8.3% of a 120 MHz block. Assuming $35 billion in unencumbered auction revenues, each 10 MHz would bring $2.9 billion (on average). Applying the 14% factor from Auction 73, an encumbered D Block would yield only $408 million in auction revenue, cutting auction revenues by about $2.5 billion.

government agency can guarantee public safety quality access to commercial spectrum on an as-needed basis.

In all, we believe the use of encumbrances will be more costly than the assignment of an additional 10 MHz in the future (as we have modeled the issue above). So that our estimates are conservative, we do not incorporate the costs of this alternative in our calculations. Any proposal adopting this option for supplying spectrum resources to the public safety network should provide a careful study of the loss of auction revenues and the dollar value of the reduced functionality and higher costs of such a network.

VI. Conclusion

The assignment of the D Block spectrum to public safety or commercial use requires an assessment of the relative benefits and costs of these two alternatives. We propose an economically sensible cost-benefit framework in the POLICY BULLETIN. An assessment of the Commission's record and other evidence within this framework suggests that D Block assignment to public safety has a higher value, producing no less than $3.4 billion more in social benefits than commercial use. Much of this difference is attributable to the unique opportunity to create a contiguous 20 MHz block of spectrum, and the fact that this opportunity exists only for the public safety community. We recognize that this issue is complex and our analysis is preliminary. That said, our work includes many of the "big ticket items", such as potential auction revenues. However, the calculations ignore any incremental benefits to society from the use of the additional 10 MHz block by the public safety community. As these gains are likely to be large, the economics seems to lean strongly in the direction of an assignment of the license to public safety. We suggest more research on this topic, but encourage future contributions to adhere to an explicit, rational framework for analysis.

At the forefront of the debate over the D Block is the potential for auction revenue. If the D Block is assigned to public safety, then the auction revenues from the 10 MHz block are forgone. The argument has been made that auctioning the spectrum will provide revenues to help fund the public safety network and perhaps aid in deficit reduction. We argue that this argument is invalid; we observe that the loss of auction revenues today are more than offset by the gain of higher auction revenues in the future and lower public network deployment costs . Thus, the auction adds, rather than relieves, stress to the public budget. Moreover, the Rockefeller bill, which allocates the D Block to public safety, also permits the use of incentives auctions to recover high-quality broadcast television spectrum that can then be re-purposed for mobile services. According to some, this spectrum is expected to generate just over $35 billion in auction revenues, the sum of which could be used for funding the public safety network and deficit reduction. Thus, while the D Block may offer a unique opportunity for the public safety network, it is not exceptional in its ability to generate auction revenues for the federal coffer.

The allocation of spectrum resources is an inherently complex issue. In the case of the D Block, complicating the choice is the fact that while the economic benefits of public safety are exceedingly difficult to quantify, the social goal of ensuring the safety of all Americans is nonetheless at stake. Fortunately, even if we value this security benefit at zero, our analysis shows that allocation to public safety is still preferred even on purely economic grounds. In our view, based on the analysis presented above, and absent evidence to the contrary, we believe the D Block should be combined in a contiguous 20 MHz block for use by the public safety community.

Public Safety Spectrum

About Rysavy Research

Rysavy Research LLC is a consulting firm that has specialized in wireless technology since 1993. Projects have included reports on the evolution of wireless technology, test reports, spectrum analysis for broadband services, evaluation of wireless technology capabilities, strategic consultations, system design, articles, courses and webcasts, and network performance measurement.

Peter Rysavy, president of Rysavy Research, specializes in the capabilities and evolution of wireless technology. He has written more than a hundred and twenty articles, reports and white papers, and has taught forty public wireless courses and webcasts. He has also performed technical evaluations of many wireless technologies including municipal/mesh Wi-Fi networks, Wi-Fi hotspot networks, mobile browser technologies, cellular-data networks, and wireless e-mail systems.

From 1988 to 1993, Peter Rysavy was vice-president of engineering and technology at LapLink where projects included LapLink, LapLink Wireless, and connectivity solutions for a wide variety of mobile platforms. Prior to that, he spent seven years at Fluke Corporation where he worked on touch screen and data acquisition products.

Peter Rysavy is also the executive director of the Portable Computer and Communications Association (PCCA, http://www.pcca.org), a group that evaluates wireless technologies, investigates mobile communications architectures and promotes wireless-data interoperability. Peter Rysavy graduated with BSEE and MSEE degrees from Stanford University in 1979. More information is available at http://www.rysavy.com.

Introduction

Through advances in technology, mass adoption, and global innovation, today's wireless networks offer tremendous voice and data capabilities. Voice coverage is reliable and ubiquitous, while data services, now commonly called mobile broadband, provide throughput rates to users of millions of bits per seconds, orders of magnitude higher than just a decade ago. New generations of wireless technology, such as Long Term Evolution (LTE), have just started to be deployed, and will deliver even greater data capabilities. LTE is the perfect choice for public safety applications. This paper will explain why 20 MHz of contiguous spectrum is essential for this technology.

This paper also discusses the emergence of LTE as a global standard, the bandwidth requirements of different applications, the relationship between spectrum and capacity, the crucial need for at least 20 MHz for public safety, and the challenges of alternate approaches that seek to share spectrum between Public Safety and commercial operators.

LTE as a Global Standard

LTE is the technology likely to see the broadest deployment of any new wireless technology over the next decade. Nearly all major cellular operators have committed to adopting LTE. The result will be huge economies of scale leading to cost-efficient services and devices. LTE not only provides high data throughput, but packets traverse the network with low delay, and traffic flow can be controlled to provide high levels of quality-of-service for applications such as video and voice over Internet Protocols (VoIP). First Responders have wisely endorsed LTE for their 700 MHz broadband networks.

Spectrum and Capacity

The amount of capacity in wireless networks depends on a variety of factors, but in general, mobile-broadband networks have significantly lower capacity than fixed-broadband networks. Capacity can be calculated by assessing the spectral efficiency of different wireless technologies, a value that is represented in bits per second per Hertz of spectrum (bps/Hz). While new technologies such as LTE are spectrally more efficient than prior technologies, all wireless technologies are reaching what is called the Shannon bound, a law that dictates the maximum spectral efficiency that a technology can achieve relative to noise.

By knowing the radio channel size and the spectral efficiency of the wireless technology, one can estimate the aggregate capacity of a cell site. LTE in its initial deployments has a spectral efficiency value for the downlink of about 1.5 bps/Hz per sector. For the uplink, it is .65 bps/Hz.[1] Thus, LTE will have the capacity values as shown in Table 1.

Table 1: LTE Capacity Values

Amount of Spectrum	Downlink Capacity	Uplink Capacity.
10 MHz (5 MHz down, 5 MHz up)	7.5 Mbps	3.25 Mbps
20 MHz (10 MHz down, 10 MHz up)	15 Mbps	6.5 Mbps

Given the application requirements discussed in the next section, these capacity values, even for 20 MHz are quite finite. The capacity in 10 MHz, as is made clear below, is simply too limiting to provide a broadband network that can accommodate the needs of first responders.

Application Bandwidth Requirements

There are multiple factors that are fueling growth in data usage including:

- **Faster networks.** The faster that data can be exchanged, the more likely it is that applications will take advantage of the speeds, especially since faster speeds can mean less waiting time for workers.
- **More network-enabled devices.** New device categories such as tablets and netbooks are expanding overall data consumption, especially because of the delivery of high-quality video. Just as consumers and enterprises are adopting these new device categories, so will first responders.
- **Increasing computing speeds.** The faster the platform can compute, the more data an application can process in real time.
- **Higher screen resolution.** Greater screen resolution corresponds to higher resolution video options for users.

[1] For a detailed discussion of spectral efficiency values, refer to my report, "Transition to 4G," September, 2010. http://www.rysavy.com/Articles/2010_09_HSPA_LTE_Advanced.pdf

- **Embedded modems.** An increasing number of laptops and tablets come with embedded 4G modems, facilitating the use of mobile broadband service.

The question is how much bandwidth do applications actually need. Some typical values are shown in Table 2:

Table 2: Application Bandwidth Requirements

Application	Bandwidth Requirements
Voice over IP	10 thousand bits per second (kbps) to 20 kbps (both downlink and uplink directions.)
General-purpose audio to record all sounds	About 100 kbps.
Video	Ranges from 200 kbps on a small-screen device like a phone, to 1 million bits per second (Mbps) for medium resolution on a laptop, to 5 Mbps for high definition.
Web browsing	Usually requires about 1 Mbps or higher to provide good response time.

By comparing these throughput requirements against the capacities listed in the previous section, one can see that just a handful of first responders could easily consume the capacity of a 10 MHz LTE network. LTE in 10 MHz has a downlink capacity of 7.5 Mbps. Thus, 8 downlink streams at 1 Mbps each would consume the capacity of the cell sector. On the uplink capacity is even more constrained at 3.25 Mbps where just 4 uplink streams would consume capacity. For example, these streams could be video from patrol cars at a crime scene.

Public-safety applications will increasingly demand higher bandwidth. The same innovation shown in commercial broadband will extend to public-safety broadband. In the February 2011 report "Cisco Visual Networking Index: Global Mobile Data Traffic Forecast Update, 2010-2015," Cisco predicts a 92% compound annual growth rate in mobile traffic. There is no reason that such trends do not also apply to Public Safety. Examples of public-safety applications include:

- Wireless video surveillance.
- Aerial video from a helicopter over a scene fed to personnel below.
- Video-based training to remote emergency workers.
- Real-time license plate recognition.
- Testimony based on video transmitted from an emergency-services vehicle or command post.
- Sending and receiving high-resolution pictures.
- In-field biometrics (such as iris and fingerprint identification).
- Automated vehicle location and navigation.
- Medical applications such as telemedicine, patient records, and high-resolution video to enable medical services performed at a scene of an accident.

It is important to note that another aspect of some public-safety applications is that they demand bandwidth continuously. For example, a patrol car in an emergency situation may need to transmit a constant video stream.

The Need for 20 MHz

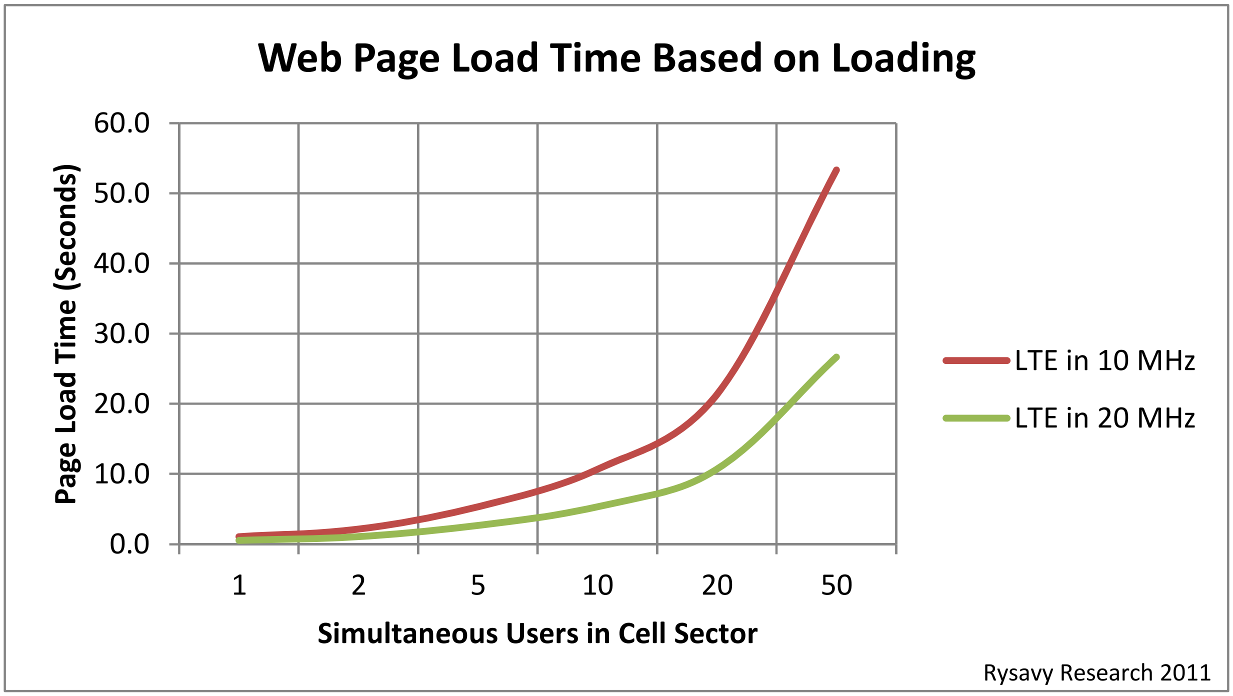
In light of the finite capacities of LTE as discussed above and growing bandwidth demands of public-safety applications, my view is that 20 MHz of spectrum for LTE is the absolute minimum to satisfy the needs of law enforcement. The available throughput per user goes down as the number of users increases. Given that many broadband applications need 1 Mbps or higher throughput, sector capacity can be exhausted quickly.

While commercial operators can design their networks for typical densities of mobile users, emergency situations can result in needing to support extremely high densities of public-safety workers. For this reason alone, the public-safety network has to have as high a capacity as possible. The network must have at least 20 MHz of spectrum. Anything less could lead to catastrophic consequences due to applications performing unreliably or failing completely.

The consequence of insufficient spectrum is restricted capacity, which combined with high demand, causes network congestion. For applications, this means sluggish behavior or outright failures.

Figure 1 shows an example of how an application begins to respond extremely slowly as the number of simultaneous users increases. Assuming a Web page of 1 MByte size, a page load time of 10 seconds (considered very slow) occurs with 10 users in a 10 MHz deployment scenario but not until 20 users in a 20 MHz deployment scenario.

Figure 1: Web Page Load Times Based on Simultaneous Users



Beyond sluggish performance in congestion situations, there is also the high likelihood that networks simply have to drop packets of data. Packets arrive at a base station over a high-speed connection such as fiber but then the base station forwards the packets using the slower radio connection. If there are too many incoming packets the inevitable result is that the base station, or infrastructure nodes prior to the base station, will drop or significantly delay packets.

Consequences of such congestion are not just slower performance but also application failures. Most communications protocols implement timeouts on their operations, including Transmission Control Protocol (TCP) itself, the packet-transport protocol used in the Internet to provide reliable end-to-end delivery. With large delays or dropped packets, communications protocols attempt to deliver data reliably, but at some level of congestion, they can no longer cope properly, and applications will either indicate a failure, or worse yet, require an application or full-system restart.

Beyond needing 20 MHz just to satisfy bandwidth requirements, there are compelling reasons for providing Public Safety 20 MHz of contiguous spectrum.

- LTE is spectrally more efficient operating in 20 MHz channels than 10 MHz channels. In other words, the network can deliver more bits per second using a 10 MHz radio channel (10 MHz down, 10 MHz up) than in two 5 MHz radio channels.
- Using non-contiguous radio channels will significantly increase the cost of the radio-access network due to the need for additional radios and antennas.
- Adding spectrum later in a non-contiguous manner will result in devices in the field likely not being able to take advantage of the new spectrum.

Challenges in Sharing Spectrum

There are arguments for alternative approaches to dedicating spectrum for Public Safety, such as sharing commercially-allocated spectrum between first responders and commercial operators, with the commercial operator serving as the primary user or licensee. This is a bad idea for a multitude of reasons.

The first reason is that the needs of commercial customers and Public Safety are inherently different. Commercial networks are developed in a highly competitive environment where operators invest in a way to provide services at the lowest possible cost to customers. These low costs are a major factor in what is driving the broadband market. First responders, however, need hardened networks that are extremely reliable. This hardening includes items such as long-term backup power, redundant backhaul, diversified routing, and explosion-proof sheltering, thus significantly increasing the cost of the network, and likely not making it viable from a competitive aspect for the private sector.

Sharing of spectrum also assumes that public-safety applications will obtain the bandwidth they need when they need it from the commercial entity. This assumption, however, is fraught with risk for the following reasons:

- **Policies implemented by commercial operators may not sufficiently address public-safety needs.** Policies, such as reserving certain amounts of bandwidth for commercial customers, may result in insufficient capacity for public-safety applications in emergency situations.
- **Prioritization schemes may not work correctly.** In an emergency situation where there is massive demand on the network from both constituencies, it is possible that prioritization schemes will not work as planned simply because they may never have been tested under such extreme conditions.

- **Users may defeat prioritization schemes.** It is already common for users to hack their devices, especially smartphones, to access services not in their current service plans. These modifications could defeat the prioritization schemes at exactly the time they are most needed.

Nevertheless, if Public Safety has control of the spectrum and they wish to lease part of their network capacity to other entities, this can be feasible and even desirable for defraying costs, so long as Public Safety can specify the terms of such arrangements, can implement the appropriate preemption capabilities, and so long as the underlying network is built to address the specific requirements of Public Safety.

Conclusion

I strongly believe that Congress should reallocate the 10 MHz D Block (758-763 MHz and 788-793 MHz) directly to Public Safety. This will enable a national broadband network for emergency services that will address the critical needs of this country. There are many reasons to have 20 MHz of contiguous spectrum available for Public Safety, including sufficient capacity, lowest-cost network deployment, and dependable network operation in emergency situations. Not doing so places this country in unnecessary jeopardy. This is a historic, and potentially last chance to allocate 20 MHz of contiguous spectrum to Public Safety. We should not squander this opportunity.

Regulation in financial translation

Spectrum valuation—an investment approach

Anna-Maria Kovacs, Ph.D., CFA

July 2011

The National Broadband Plan calls for 500 megahertz of spectrum to be made available for use by wireless broadband over the next decade, with 300 megahertz to be made available over the next five years. Spectrum is a public asset and an obvious question is how to optimize the value and use of that asset. That question, in turn, comes down to a tradeoff between the inherent value of the spectrum itself and other public interest considerations. In other words, the amount of money that an auction can raise for the Treasury—the auction as a source of Treasury funds--is impacted at least in part by controllable decisions about how the auction configures the spectrum for sale and the conditions imposed on it.

The Congressional Budget Office (CBO) has scored the value of spectrum likely to be auctioned by 2021 at $24.5 billion [CBO scoring of S.911 on July 20, 2011]. The CBO states that it is difficult to predict the amount of spectrum that might be auctioned by 2021, because it is difficult to predict what spectrum might become available and when existing users might be moved. CBO points to past experience that relocating both federal and commercial users can be very costly and time consuming. CBO estimates that between 150 to 225 megahertz of spectrum below 3 gigahertz might be auctioned by 2021, but does not specify the mix of spectrum in the lot it is pricing out. It estimates that the weighted average unit price paid by winning bidders might be lower than in recent years, estimating it at $0.70 per megahertz (MHz) per person (POP), i.e. $0.70 per MHz/POP.

It is, of course, appropriate for CBO to provide a conservative estimate. But it might also be helpful for Congress to be able to approach the issue from another angle—looking at spectrum the way investors do--taking into consideration the enormous range of valuation that is possible for the same spectrum depending on the way spectrum is configured and the conditions that are attached to its sale. In other words, the value to be extracted from spectrum can to a large extent be influenced by Congress and the Federal Communications Commission (FCC), acting under Congress' instructions. **Looking just at the broadcast spectrum that might be auctioned during 2012-2021, using valuations in Auction 73 as a proxy, depending on the amounts auctioned and the conditions attached, the proceeds of the auction could vary from $1.4 billion to $91.4 billion.** That is, of course, an enormous range, and the reasons for it are explained below. Here we will point out only the two extremes: The $1.4 billion represents the sale of 30 megahertz with extensive conditions and the $91.4 billion represents the sale of all 120 megahertz with no conditions. Please note that this paper deals only with auctions as sources of funds, but does not comment on how those funds might be used once the auction has raised them.

There are at least two sets of issues that impact proceeds from an auction. One is market conditions and the other is the usefulness of the spectrum to bidders. The economy, the ease of getting financing, and the potential universe of bidders are key elements of market conditions. The other set of issues is the inherent value of the spectrum, as modified by conditions attached to it. The inherent value of spectrum itself is a function of its propagation characteristics. But other factors also enter the equation and determine how useful and valuable that spectrum may be to potential auction-bidders. Factors include: the geographic footprint covered by a license (CMA, EA, REAG, nationwide), the band-size, the level of interference that may be expected from neighbors and/or from other users of the same spectrum such as unlicensed users, other restrictions or conditions that may be placed on the spectrum, as well as issues specific to bidders such as other spectrum they already hold. The value obtained by the Treasury from an auction is further affected by factors such as discounts provided to designated entities for public interest reasons.

One of the recommendations of the NBP was that the FCC reclaim and auction 120 megahertz from broadcasters via incentive auctions. It is not clear how much of this spectrum is included in the CBO's scoring or at what valuation. However, that spectrum is inherently similar to the spectrum in the 700MHz band that was offered in Auction 73, which ran from January to March of 2008. In this paper, we use Auction 73 as an example of the range of values that the Treasury might be able to obtain in exchange for various amounts of the proposed broadcast spectrum under various conditions.

Market conditions in early 2008 were poor. The economy had just begun its slide into the worst recession in decades, and the stock market had taken its first slide off its high point, but had not yet gone into complete free fall. The collapse of Bear Stearns on 3/18/2008 coincided with the end of auction 73, but the credit markets had begun to freeze up in late 2007, making it difficult for bidders without well-established track records to get financing. Frontline Wireless, which had been expected to lead the bidding for the D-block had to withdraw for lack of funding, despite stellar and normally very credit-worthy leadership. Thus, while the FCC did not exclude any potential bidders from the auction, the economy did so.

There are reasons to expect that there will be solid demand for spectrum in auctions during the 2012-2021 timeframe. Cisco has predicted that mobile data traffic will grow 92% per year for the next five years, driven by video. Credit Suisse issued its *Global Wireless Capex Report* on July 18, 2011 indicating that capacity utilization in U.S. networks is at 80%, well above target rates. Credit Suisse expects companies to increase capital investment in the next few years to wring all possible capacity out of the existing spectrum. But, as Rysavy Research points out in its March 16, 2011 engineering analysis of spectrum use, a report titled *The Spectrum Imperative*, there is a limit to what can be accomplished simply through more intensive network engineering. Without enough additional spectrum, network performance will suffer. As the CBO points out, the process of identifying spectrum for sale, designing and holding the auction, then clearing the spectrum for use post-auction takes several years. Bidders will plan their bids based on spectrum needs far down the road, at a point when efficiencies gained via network investment and upgrade in the 2011-2013 period will have been exhausted. If the National Broadband Plan was right and 500 megahertz are needed by 2021, and if the CBO is right that only about 30%-40% of that can be brought to market by 2021, then demand for spectrum should result in a very strong auction-bidding environment. That demand will be further enhanced if the CBO is right that the spectrum will have to be auctioned in multiple stages, so that no single auction places a glut of spectrum on the market.

While it is impossible to predict what market conditions will be when the FCC auctions spectrum over the next decade, Auction 73 provides a proxy for an auction performed under poor, if not yet completely disastrous, conditions. In other words, the market and demand environment for the auctions over the next decade are likely to be healthier than the environment was for Auction 73. And, of course, all of the blocks sold in Auction 73 were sold under the same set of market conditions, since they were all sold at the same time. In this paper, we are not predicting a specific price for spectrum in future auctions, but suggesting a reasonable proxy as well as illustrating factors that influence valuation under a given environment.

Auction 73 provides an outstanding illustration of the broad range of values that similar spectrum can attain depending on factors that are largely under the control of the FCC, such as spectrum configuration and public-interest conditions. The spectrum was divided into 5 sets of blocks, A, B, C, D, and E. The range of average final bids for these blocks ranged from $0.17 per MHz/POP for the D-block to $2.67 per MHz/POP for the B-block, for inherently similar spectrum. As described below, there were various reasons for the differences in valuation. The A-block's value was suppressed mostly by concerns about interference from the neighboring broadcast channel 51. The E-block's value was suppressed by the fact that it was a narrow, unpaired channel whose uses were inherently limited. The C and D blocks' values were suppressed mostly by the public-interest conditions that were attached to these blocks. The B-block is the best proxy for the value that can be obtained for clear spectrum that is free of conditions.

A and B were 12 megahertz wide each, and consisted of paired 6 megahertz blocks. C was 22 megahertz wide and consisted of paired 11 megahertz blocks. D was 10 megahertz, in the form of paired 5 megahertz blocks. E was an unpaired 6 megahertz block. Other characteristics included:

- Geographic coverage: A and E were auctioned by Economic Area (EA), B was auctioned by Cellular Market Area (CMA), C was auctioned by Regional Economic Area Grouping (REAG), and D was nationwide. There were 176 licenses each in the A- and E-blocks, 734 licenses in the B-block, 12 licenses in the C-block, and one in the D-block. Each license within a block represents a different geographic area. The CMA areas are smaller than the EA areas, which in turn are smaller than the REAGs, which are smaller than the nationwide area. The licenses—i.e. areas—could be combined like building blocks, so that a collection of licenses could be built into a larger area. For example, Verizon bid on REAGs, but could effectively combine the areas it won into a national footprint covering the lower 48 states.
- A was impacted by potential interference from broadcast Channel 51.
- C carried an open access condition—unlocking and unblocking. The winner of this spectrum agreed to allow porting of devices and access to any applications, subject to reasonable network management.

- D carried a variety of conditions with regard to its relationship to public safety spectrum.
- E's uses were limited by its unpaired nature.

The average value of these blocks was:

- A: $1.16
- B: $2.67
- C: $0.76
- D: $0.17
- E: $0.74

The lowest bid per MHz/POP of $0.17 was obtained for the D-block, which was heavily conditioned, required coordination between the buyer and public safety, required the winner to fund public safety's buildout as well as its own, and gave public safety priority access to the spectrum when needed but also gave the D-block winner access to public safety spectrum when it was unused. We view this as a proxy for appealing spectrum that carries extremely unappealing public-interest conditions. While in theory this spectrum was open to any bidder, the conditions were so onerous that they effectively discouraged most bidders. The tough financial conditions of the time precluded the most likely bidder—Frontline Wireless—from participating.

The second lowest bid of $0.74 was obtained for the E block which consisted of 6 megahertz of unpaired spectrum, bid by EA. In this case, the key deterrent was the unpaired nature of the spectrum. This is a proxy for less appealing spectrum (because unpaired) that does not carry conditions that might have further lowered its valuation.

The third lowest bid of $0.76 per MHz/POP was for the C block. The C-block had the advantage of being 22 megahertz wide and thus easily suited to use for broadband. It is not clear whether its division into REAGs, large geographic regions, helped or hurt valuation. For some bidders, it might have been attractive that the REAGs could easily be combined into a national footprint, while other bidders might have preferred smaller areas because those would require building out less territory and thus involve less cost. The C-block also carried open access conditions—unlocking and unblocking—which appear to have deterred bidders. We view this as the best proxy for spectrum that is inherently very attractive but carries unappealing public-interest conditions.

The second highest valuation of $1.16 per MHz/POP was for the A-block, which was bid by EAs, areas smaller than REAGs but larger than CMAs. The main deterrent here appears to have been potential interference from broadcasters on channel 51.

The highest valuation of $2.67 per MHz/POP was for the B-block, which was bid by CMAs (the smallest market size), which was not threatened by interference, and did not carry conditions. Thus, we view this block as the best proxy for valuation of clear spectrum free of conditions.

As the accompanying table shows, the value of the full 120 megahertz of broadcast spectrum could vary from $5.7billion to $91.4 billion, depending on the conditions attached. [Please note that, for comparability, we are using the same number of POPs that were used in Auction 73, i.e. 285.62 million POPs., while recognizing this number may be a bit low by now.] The letters on the left in the table stand for Auction 73 blocks that are proxies. The lowest valuation would involve heavy conditions like those that were attached to the D-block, while the highest valuation would involve spectrum that is neither threatened by undue interference nor carries conditions, i.e., similar to the B-block. The proceeds, obviously, also vary by the amount of spectrum sold. Thus, condition-free spectrum like the B-block could bring $22.9 billion for 30 megahertz, $45.7 billion for 60 megahertz, and $68.6 billion for 90 megahertz.

It is also possible to consider variations. For example a total of 90 megahertz could bring $52.2billion in a combination of $45.7 for 60 megahertz without conditions combined with $6.5 billion for 30 megahertz carrying conditions like those carried by the C-block. It could alternately bring $47.1 billion if 60 megahertz carried no conditions and the other 30 megahertz was conditioned as heavily as the D-block was in Auction 73. Many variations of amounts of spectrum and level of conditions are possible, and the resulting proceeds can be calculated from the table below.

The bottom line is that Congress has tremendous discretion about the amount of proceeds it could raise in exchange for spectrum. Looking just at the broadcast spectrum, depending on the amounts auctioned and the conditions attached, the auction could raise between $1.4 billion for 30 megahertz of heavily-conditioned spectrum to $91.4 billion for 120 megahertz of spectrum that carries no conditions or bidder-restrictions. Additional funds would, of course, come from the auction of other spectrum in addition to the broadcast spectrum.

The CBO provided one estimate of the value of the spectrum that might be auctioned between 2012 and 2021, and that estimate is, of course, important. Given the strong demand for spectrum that is likely and the difficulty of finding enough spectrum, the actual amount could be much higher, if even just a portion of the broadcast spectrum is auctioned, as long as the bidding is open to all possible bidders and no conditions are so onerous as to discourage bidding by either incumbents or potential new entrants.

Valuation of broadcast spectrum

	Number of megahertz			
	30	60	90	120
A	9,903	19,806	29,709	39,612
B	22,860	45,720	68,580	91,440
C	6,475	12,950	19,425	25,900
D	1,416	2,832	4,248	5,665
E	6,334	12,669	19,003	25,338

700 MHz
Broadband Public Safety Applications And Spectrum Requirements

February 2010

CONTENTS

Preface

Since the Public Safety Wireless Advisory Committee (PSWAC) report was released in September 1996, the wireless communications landscape has undergone enormous changes. While it is true that technology has allowed for more efficient use of spectrum resources, it is equally true that public safety's need for spectrum has never been greater. In 1996 there were no broadband wireless networks or applications. Public safety's need for data communications was limited to text in the form of digital dispatch. Even then there was a shortage of spectrum available to public safety. In the interim, public safety wireless networks have continued to fall behind commercial networks in technology and capability.

Today we are at a crossroads. We can either advance public safety communications by consolidating our efforts and resources to create a nationwide public safety broadband interoperable network that supports both data and voice or we can continue to support separate networks on disparate frequency bands using incompatible technologies. We are under no illusion and fully understand that this is a formidable challenge. The vision of a converged public safety data and voice network will not be realized for several years, and then only when public safety is satisfied that broadband mission critical voice is as reliable as existing land mobile mission critical voice networks. Nevertheless, we also understand that if we do not have sufficient spectrum resources, we will never achieve our goal.

Public safety needs additional broadband spectrum that is suitable for both current and future technologies such as streaming video, automated license plate recognition, and biometric technologies including mobile fingerprint and iris identification. The 700 MHz band is ideal for public safety as it provides superior coverage and "in building" performance compared to higher frequency bands. It is imperative that public safety control this spectrum to ensure that the standards established for the Public Safety Nationwide Broadband Wireless Network regarding capacity, interoperability, priority and reliability are maintained at the highest level. Recent incidents have illustrated that commercial wireless services cannot provide the bandwidth and services needed during an emergency.

The existing public safety 700 MHz spectrum allocation is inadequate to support public safety requirements. The D Block spectrum is crucial to the development of the nationwide network because it is adjacent to the existing public safety broadband allocation. Combining the existing public safety 700 MHz spectrum with the D block will simplify network design and deployment, and will reduce handset and mobile device costs. A single wireless broadband network combining the D Block and the adjacent public safety 700 MHz spectrum is the only logical choice to satisfy public safety broadband wireless spectrum requirements. All major national organizations representing police, fire, emergency medical and prominent public safety officials have united in an unprecedented effort to support the reallocation of the 700 MHz D Block spectrum to public safety, and the creation of a truly interoperable public safety wireless broadband network.

Executive Summary

Public safety must plan now for existing and future wireless broadband needs. Many broadband applications are already being used by public safety, often using commercial networks. Public safety envisions utilizing additional broadband applications but requires public safety grade coverage, redundancy and infrastructure hardening conspicuously lacking in commercial wireless networks. This paper lists and describes many public safety wireless broadband applications and their spectrum requirements. As new commercial broadband applications are developed, some of them will undoubtedly benefit public safety agencies.

The currently proposed 700 MHz spectrum allocation is insufficient to support the applications that public safety requires now. The 700 MHz "D block" spectrum scheduled for auction is adjacent to the Public Safety Broadband Licensee (PSBL) 700 MHz Broadband allocation. The adjacent spectrum is critically needed to provide the capacity necessary to support mission critical public safety broadband applications now and in the future. A single wireless broadband network spanning both the D Block and the adjacent public safety 700 MHz spectrum is the only logical choice to support public safety requirements.

Most commercial wireless carriers have committed to deploying a fourth generation wireless technology called Long Term Evolution (LTE). This technology will be deployed worldwide and is supported on the 700MHz band. Once these commercial broadband LTE networks are deployed, public safety will gain access to lower cost infrastructure and user devices, and will reap the benefits of ongoing research and development financed by the commercial wireless industry.

The 700 MHz band is ideal for public safety as it provides superior coverage compared to the higher bands in mountainous terrain and within buildings. If the 700 MHz D Block is auctioned to commercial providers, the lack of available spectrum will force public safety to maintain separate wireless networks for data and voice in perpetuity, forcing public safety to financially support two networks and carry two devices.

A 700 MHz public safety nationwide broadband wireless network supporting both data and voice will for the first time establish true interoperability in public safety emergencies requiring a multi jurisdictional response. The September 2009 Draft of the National Broadband Plan lists an eventual converged data and voice network for public safety as a strategic goal[1]. This vision will never be realized without a commitment by the Federal government to allocate the D Block to public safety now. Auctioning the D block is shortsighted and ultimately prevents public safety from attaining its goal of a dedicated, robust and reliable broadband wireless network. We believe that the future cost savings achieved by a converged public safety data and voice network will far

---

[1] See Draft National Broadband Plan Dated September 29, 2009 Page 9, National Priorities, Public Safety "Interoperable mission critical voice and broadband network".

outweigh any short term revenue collected from a second auction of the D Block spectrum.

The benefit of allocating the D Block to public safety is very significant while the cost of reallocating the spectum is very small. The Cellular Telecommunications Industry Association (CTIA) has indicated that approximately 800 MHz. of additional spectrum is needed to enable commercial broadband service[2]. While allocating 10 MHz. of spectrum in the D Block would double the broadband spectrum for public safety, removing it from auction represents a reduction of only 1¼ percent of the spectrum requested for commercial broadband. Dedicating additional spectrum for public safety broadband would benefit the entire population, who are served by dedicated Police Officers, Firefighters and Emergency Medical personnel. We therefore urge Congress to place a priority on public safety by directing the Federal Communications Commission to reallocate the D Block to public safety broadband operations.

Appendix A, is an excerpt from New York City's recent Comments filed with the Commission in the Matter of Additional Comment Sought on Public Safety, Homeland Security, and Cyber security Elements of National Broadband Plan -- NBP Public Notice # 8. The excerpt is included at the end of this document to underscore our major points and provide broadband throughput analysis data.

Section One

Public Safety Requires a Robust and Reliable Network

Reducing public safety coverage, reliability or availability requirements in order to attract potential bidders is shortsighted as such a network will not meet public safety's needs. The result will be a false sense of security that will be shattered by catastrophic network failure when the first large scale disaster occurs. All commercial enterprises are motivated by profit, commercial wireless networks are no exception. Their primary responsibility is to their shareholders, not to the welfare of the public.

Public safety's mission is to protect the public, there is no profit motive. Therefore, Public safety communications networks are more akin to military wireless networks rather than commercial wireless networks. The establishment of the Department of Homeland Security and the FCC's recent establishment of the Public Safety and Homeland Security Bureau, as well as the longer established position of Defense Commissioner all serve to underscore the increased threats that public safety agencies must contend with in the post 9/11environment.

[2] Letter from Christopher Guttman-McCabe, Vice President, Regulatory Affairs, CTIA, to Chairman Julius Genachowski, *et al,* Federal Communications Commission, GN Docket No. 09-51, September 29, 2009 ("CTIA Spectrum Needs").

Reducing the minimum required bid price undercuts the very purpose of the auction. Diluting the network coverage and reliability requirements shortchanges public safety. Rather than taking these steps to attract a potential bidder, we urge Congress and the Commission to cancel the D Block auction and assign the D block directly to public safety. This will insure that public safety has sufficient spectrum to deploy a nationwide interoperable mission critical wireless network that will ultimately support both voice and data, alleviating interoperability issues caused by legacy public safety networks operating on disparate frequency bands and incompatible wireless technology platforms.

Section Two
Benefits to Public Safety

Network Control
If public safety owns and operates its own network, or at a minimum holds the spectrum license in a public private joint venture network, they can exert greater control over future technical decisions that effect network performance. Additionally, ownership of the network allows public safety to exert influence over the network design and deployment to satisfy the immediate and future needs of public safety users.

In an emergency it is critical that public safety exert direct control over their critical communications networks. Public safety agencies must be assured that they are afforded the highest priority during emergency situations, even if others are denied service or are otherwise inconvenienced.

The addition the D block licensed to the public safety 700 MHz. allocation will put public safety in a favorable position if a public safety partnership is forged in a particular locality. Other localities may choose to build own and operate their own public safety broadband network. In either case, granting the license for the D Block spectrum through a public safety entity such as the PSBL puts public safety agencies in a better negotiating position if a partnership arrangement is desired. As licensee, public safety will be able to partner with any qualified commercial entity whereas if the D Block is auctioned, public safety can only negotiate with the D Block auction winner.

Guaranteed Access
In order to protect the public and perform their job efficiently and effectively, public safety users require guaranteed access to the communications networks they use. In recent years, public safety users have become increasingly reliant upon commercial networks. During emergencies these networks often fail due to congestion or infrastructure breakdown, since they are not scaled or engineered for emergencies.

On October 11, 2006 New York Yankee pitcher Cory Lidle crashed a small private plane into a 40 story apartment building in Manhattan. Public safety first responders arriving at the scene were unable to use their commercial wireless cell phones due to call blocking resulting from network capacity limitations. All wireless carriers were similarly affected.

Although many of the first responders had "priority access" they were still unable to access the wireless networks in most cases.

Analysis after the event revealed that a large part of the problem was that the commercial wireless networks are simply not scaled and engineered to handle the traffic spikes that result from this type of event. Further analysis revealed that "priority access" was ineffective for two reasons. First, the priority given to public safety is only "top of the queue" priority, rather than preemptive access. Given the location of the incident and the number of news media personnel present, who have learned from experience never to end their call until the incident is over, it is not surprising that few public safety calls were successful. The second factor is that the "access channel" was congested. The network could not recognize the public safety user as a priority user until the call request was recognized by the network. Since the access channel was overwhelmed, the public safety user was competing with all other users for network recognition.

Future Cost Avoidance

Both the National Public Safety Telecommunications Council (NPSTC) Statement of Requirements for the National Public Safety Broadband network and the FCC Third Further Notice of Proposed Rulemaking specify a Push to Talk (PTT) voice capability. As LTE technology matures, we are confident that a mission critical voice capability will become a reality. Setting aside sufficient spectrum for this purpose now will create a more definitive market opportunity for technology suppliers to begin early development of products knowing that a true market exists and that development costs can be recovered through sales of equipment and systems.

In the future we envision a single converged voice and data network for public safety. This vision is also expressed as a national strategic goal in the September 2009 Draft of the National Broadband Plan. If a converged public safety voice and data network becomes a reality, public safety agencies will reap significant cost savings since they will only have to support a single wireless communications network and carry a single device for both data and voice.

At the recent GSMA (Groupe Spéciale Mobile Association) Mobile World Congress, the GSMA announced the acceptance by the majority of wireless network operators of a standard for voice over Long Term Evolution (LTE). The technology will be based on IMS (Internet Multimedia Services). The GSMA believes that IMS voice services could become available over LTE as soon as the middle of 2011.

Reliability

Public safety networks are typically equipped with emergency power backup capability. Most critical public safety radio sites are equipped with a minimum of eight hours of backup power. During the Northeast blackout of August 2003 many cell sites in New York City failed within the first few hours and remained inoperative for the duration of the blackout.

Network Restoration
Public safety staff can restore service quicker than commercial entities. Public safety technical staff can more quickly access sites within disaster areas when commercial providers (civilians) are excluded due to security concerns.

Technical Staff
Public safety technical staff will respond in situations that commercial providers will not. Public safety technical staff are credentialed and screened to a higher standard than commercial provider technical staff and their subcontractors. Commercial providers often use third party subcontractors who are not focused on public safety as their primary commitment. They sometimes employ transient workers whose commitment to the mission is questionable. Such employees are rarely subjected to extensive background checks prior to employment.

During the Northeast blackout of August 2003 electrical power was out in most of New York City for approximately 25 hours. This exceeded the backup power capacity at many NYPD radio sites. However, NYPD Radio Repair Mechanics and Police Officers were able to keep these sites on the air by replacing discharged backup batteries with freshly charged batteries. These batteries weigh approximately 100 pounds and in some cases had to be hand carried up sixty floors. No commercial wireless network provider made a similar effort to maintain service, nor would we expect them to. They simply waited for commercial power to be restored.

Section Three
Long Term Evolution and Spectrum Efficiency

Long Term Evolution (LTE) has been endorsed by the Public Safety Spectrum Trust (PSST), the Association of Police Communications Officials (APCO), the National Emergency Number Association (NENA), and the National Public Safety Telecommunications Council (NPSTC) as the preferred technology for 700 MHz. Public Safety Broadband Network. Verizon Wireless, AT&T, and T-Mobile have all publicly stated their intention to deploy LTE in the United States as their fourth generation (4G) wireless network.

LTE standards are governed by the Third Generation Partnership Project (3GPP), an international wireless standards body. LTE is supported by the 3GPP and most commercial wireless carriers, worldwide. LTE supports channel bandwidths from 1.5MHz. up to 20 MHz. wide.

Spectrum efficiency is improved through spectrum aggregation. The larger the channel size the greater the potential for spectral efficiency. Within LTE, a 10MHz. block of contiguous spectrum provides significantly greater spectrum efficiency than two 5MHz. blocks of non contiguous spectrum blocks.

The current allocation for broadband public safety spectrum consists of two 5 MHz. spectrum blocks, one 5MHz. uplink channel and one 5MHz. downlink channel. Although a public safety broadband network could be created using 5MHz. uplink and downlink channels in the existing public safety broadband spectrum, and another commercial LTE network, could be deployed using the 5MHz. uplink and downlink channels in the adjacent D Block. A better solution is for public safety to be allocated the D Block channels and deploy a network consisting of two 10 MHz. LTE channels, one uplink and one downlink. This solution offers distinct advantages. First, it is more spectrum efficient as it allows higher peak power data rates and higher throughput. Second, it is more economical since the cost to deploy a network consisting of two 10 MHz. channels is approximately the same as the cost to deploy two 5MHz. channels.

The 700 MHz. D Block is the only available spectrum adjacent to the public safety broadband allocation. If the D Block is auctioned rather than being assigned to public safety, state and local governments will pay a much higher price in the future supporting public safety communications than any short term revenue gleaned through a second auction. If a commercial wireless provider chooses a technology other than LTE for the D Block, a guard band will have to be established between the D block and the Public Safety broadband spectrum.

LTE supports channel sizes ranging from 1.5MHz up to 20MHz. A network utilizing larger channels in urban environment will provide substantially greater capacity. In rural areas, larger channels will allow for the deployment of a higher site architecture network employing higher power base stations thereby reducing the number of sites required.

Section Four

Convergence of Data and Voice

As time goes on, it will become increasingly more attractive to build converged data and voice networks. This issue was raised during the PSWAC effort in 1996; however it was not technically feasible at that time. The technical environment has changed dramatically since then. A converged data and voice network solution at 700 MHz is now possible if the Federal Government, public safety and the wireless communications industry decides to move in that direction. It will not be possible if the spectrum is not available.

The National Public Safety Telecommunications Council's (NPSTC) Statement of Requirements published in November 2007[3] and the FCC Third Further Notice of Proposed Rulemaking issued in September 2008[4] both specify a commercial grade PTT voice capability as a requirement of the Public Safety 700 MHz. Broadband Network. We are confident that over time a mission critical voice capability will be developed within the LTE framework.

[3] See NPSTC Public Safety 700MHz Broadband Statement of Requirements pp20-21
[4] See FCC Third Further Notice of Proposed Rulemaking Appendix C, p189(4) and p193 (Table 1)

Federal Agencies are already beginning to use converged voice and data networks for mission critical communications.

> "The vast majority of Federal public safety agencies do not currently use broadband networks to support mission-critical voice communications. The Transportation Security Administration (TSA) of the Department of Homeland Security (DHS) is one exception. TSA uses commercial wireless broadband services in the 800 MHz spectrum for mission critical air to ground communications for Federal law enforcement officers in flight, as that is the only spectrum available for this application. This capability will soon include Voice over Internet Protocol (VoIP)."[5]
>
> "Immigration and Customs Enforcement (ICE), within DHS, is another exception. ICE uses commercial broadband networks for intranet access for laptops and other portable electronic devices, such as Blackberries, and for voice telephony applications. ICE requires exceptionally stringent security to safeguard law enforcement information and therefore allows broadband access only for authorized ICE end user equipment on which the required security controls have been installed and tested. ICE's law enforcement officers have mission-critical requirements for critical demand theater operations. The lack of law enforcement priority on commercial broadband networks also necessarily limits ICE's usage of such systems. Despite such limitations, the Commission should consider whether use of commercial broadband networks, with adequate adoption by public safety agencies, may be a first step in the path to maximized broadband network."[6]

The National Telecommunications and Information Administration (NTIA) shares the view that a converged public safety data and voice communications network will ultimately replace existing narrowband public safety voice networks.

> "As voice and data communications continue to converge, users have a greater expectation for both voice and mobile wireless data capabilities. Broadband systems that can provide reliable, interoperable voice and data systems will likely replace antiquated narrowband voice systems and low data rate networks. If mission critical voice applications are to migrate to broadband, systems will need to have sufficient control channel capability in high congestion areas, especially during special events and large gatherings, to support both a significant increase in text messaging and data traffic and call setup capability for national security and emergency preparedness (NS/EP) communications. Legacy voice networks must be effectively leveraged while the migration to broadband evolves." [7]

---

[5] See NTIA Executive Branch Views On Public Safety, Homeland Security and Cyber security Elements of a National Broadband Plan, December 2009; Page 4.

[6] See NTIA Executive Branch Views On Public Safety, Homeland Security and Cyber security Elements of a National Broadband Plan, December 2009; Page 4.

[7] See NTIA Executive Branch Views On Public Safety, Homeland Security and Cyber security Elements of a National Broadband Plan, December 2009; Page 11.

Assuming that the 700 MHz. broadband public safety network will be constructed in any event, public safety should seize this opportunity to include mission critical voice as a required network component as soon as the technology permits, thereby solving voice interoperability issues and standardizing public safety communications nationwide. We realize that mission critical voice over broadband is a not available today and that public safety will not accept this technology until it equals or exceeds the capabilities and reliability of existing mission critical public safety land mobile radio networks. However, we also believe that the eventual convergence of broadband data and mission critical voice on a single network is inevitable. The alternative is to support separate public safety networks for data and voice, construct and maintain incompatible mission critical voice networks using dissimilar technologies on disparate frequency bands, and pay premium prices for narrowband user devices. We view this alternative as unacceptable.

The goal of public safety communications planners should be not only consolidation onto an integrated broadband voice and data network[8], but also an orderly migration of existing public safety mission critical voice communications systems, over time, to a common frequency band and technology platform, which will provide inherent interoperability and improved spectrum efficiency while reducing overall costs in the long term. In order to achieve these objectives, Congress should allocate the 700 MHz. D Block directly to public safety and forgo a second auction.

Section Five
The 4.9GHz. Public Safety Spectrum

Some opponents of our effort to assign the 700 MHz D Block to public safety have suggested that the public safety 4.9 GHz channels provide more than enough spectrum for public safety to deploy broadband networks. The deployment of wide area networks using 4.9GHz public safety channels is impractical for several reasons. First, the number of sites required to provide adequate coverage, especially in an urban environment is staggering. The number of sites estimated to cover New York City alone exceeds 13,000. From both a maintenance and infrastructure perspective 4.9GHz is a poor choice. It may be appropriate to use this technology in small areas for special purposes; however the poor propagation characteristics offset any derived benefit. In some localities 4.9 GHz has been used to implement wireless WANs, however this was done out of necessity, since no other spectrum was available. Currently, there are no other options available to public safety for a broadband network deployment. Another very critical issue is the backhaul requirements of a 4.9GHz wide area network; the number of sites required to provide ubiquitous coverage creates a difficult challenge to deliver backhaul infrastructure to the network. The 4.9GHz public safety channels were intended for hotspot or incident scene use only; they were never intended to be used as a wide area

[8] See Draft National Broadband Plan Dated September 29, 2009 Page 9, National Priorities, Public Safety "Interoperable mission critical voice and broadband network". Page 161 Ensuring public safety requires a high quality network; Goal:" Enhances mission critical voice over time"

network solution. 4.9GHz links can be used to transport video for spontaneous or temporary deployment over short distances.

Public safety emergencies occur in all areas, not merely in pre-defined or anticipated locations. Time is of the essence when lives are at stake. It is far more desirable for public safety first responders to have a wireless network in place that provides adequate broadband coverage in all locations than to call in a special unit to deploy an ad-hoc network. Incidents that unfold quickly or change locations further underscore the need for ubiquitous broadband network coverage rather than relying on ad- hoc networks to be set up and broken down repeatedly. Fixed wireless network assets are a much more permanent, reliable and effective solution for public safety.

The propagation characteristics of 4.9GHz virtually preclude practical wide area network deployment since the range is very limited. Although it is possible to deploy a mesh network to increase the range and circumvent obstructions, this technique severely reduces throughput and adds additional layers of complexity and potential failure. Due to the specifications of the 4.9GHz emission mask, devices deployed on adjacent channels in close proximity may interfere with each other, further reducing throughput.

Connectivity between 4.9GHz devices requires a line of sight path between transmitter and receiver; 4.9GHz signals will not bend around obstructions. These physical channel limitations are especially problematic for deployment in dense urban areas which are the very areas most likely to require the highest data throughput. The inability of 4.9GHz signals to penetrate walls, windows and other common construction materials render them virtually useless indoors.

A wide area 4.9GHz network deployment is inconsistent with the ultimate goal of a constructing a converged nationwide voice and data public safety network utilizing a single user device and operating on a common technology platform. The suggestion that 4.9GHz devices can be deployed over a wide area to provide broadband capability for public safety first responders ignores the coverage limitations of the frequency band. The 4.9GHz public safety channels are more appropriately used as hotspots at known congregation points such as Police Precincts or Firehouses, or at the scene of protracted incidents for the local exchange of broadband data and for Blue Force Tracking purposes.

The majority of public safety broadband applications will require backhaul to remote data bases so that information can be downloaded to public safety responders and to Command and Control facilities so that critical information can be exchanged between headquarters and field units. Ad-hoc 4.9GHz hotspots deployed at incident scenes without the benefit of backhaul do not provide the same level of functionality as access to a permanently installed wireless infrastructure.

Municipal Wi-Fi mesh networks deployed within the last few years by some governmental agencies and private firms have, for the most part, been shut down. This occurred due to the lack of a sound business model, the need to constantly add and relocate access points, the cost of back-haul for these networks and poor in building penetration. The inability of well funded commercial entities to successfully deploy Muni Wi-Fi networks in the lower portion of the spectrum where coverage is better than at 4.9GHz. indicates that this model is not a suitable alternative to the 700 MHz wide-area network planned for public safety.

Section Six
Public Safety Broadband Data Applications

Applications Relevant To All First Responder Agencies

1.) Incident Video
Live incident video has immeasurable benefits to public safety. The ability to stream on-scene video to responding units, operations and communications centers, supervisors and emergency managers can dramatically alter the way public safety responds to major incidents. The ability to share first responder and broadcast video among responding agencies will greatly enhance public safety's ability to manage and contain critical incidents. Integrating Geographic Information System (GIS), sensor and tactical data with video will provide first responders with critical pre-arrival information that will allow a more effective response to critical incidents. Video captured at incident scenes can be wirelessly transmitted to Command and Control facilities or responding mobile units, improving situational awareness and enhancing officer safety.

Incident Video Viewing DL	1150 kbps
Incident Video Viewing UL	28 kbps

2.) Broadband Data Dispatch
Although "digital dispatch" has been available for more than 20 years, its capability has been limited largely to text transmissions by the throughput constraints of current narrowband public safety wireless data networks. A next generation public safety broadband data network will allow broadband data to be transmitted to field units prior to their arrival at the incident location, greatly improving situational awareness.

Advanced consumer wireless features such as photos and video sharing allow citizens to capture incident information and transfer it to public safety dispatch centers. Utilizing a broadband network this information can be wirelessly transmitted to field units responding to an incident. Additionally, this capability will allow dispatchers to attach this information to the incident record, automatically send it to responding units to view or listen to all available data related to the job assignment, including for example an audio file containing the information provided during a 911 call. It will provide critical premises history information such as: prior police response, arrests, weapons, warrants, and crime report histories. This type of information can be critical in determining how the responding officers approach the individuals involved in the incident, or enable them to more effectively conduct their investigation. Broadband data dispatch will reduce radio traffic on voice channels, minimize call backlog, improve response time, improve officer productivity and enhance officer safety.

The NYPD currently responds to an average of 5,000 to 6,000 incidents per day. Over time, the voice component of the public safety dispatch function will decrease, while the broadband data component will increase dramatically. We envision that in the future, pushing broadband data to responding field units will account for 85 to 90 percent of dispatch transactions without the need for voice communications.

3.) Mobile Incident Command Vehicles

During major incidents and special events, specialty vehicles are dispatched to serve as Mobile Command Posts. These vehicles are typically equipped with multiple communication devices and critical incident management applications and contain radios, cell phones, fax machines and satellite phones. Wireless broadband connectivity will allow two-way transfer of photos, video, and audio clips to and from Headquarters in real time, improving Command and Control and situational awareness for on scene Incident Commanders as well upper echelon command staff not on scene. Additionally, applications that require high bandwidth connectivity can be supported at the incident scene over a single broadband modem.

SFTP Transfer UL	92 kbps

4.) Mobile Access to Geographic Information System (GIS)

Mobile units and field commands can download geographic information such as topographical and curb line maps and architectural and computer rendered drawings from government and private municipal data bases. Use of GIS and Computer Aided Drafting and Design (CADD) information will provide invaluable assistance to law enforcement and fire services during routine and major incidents. Incidents such as the Mumbai, India Hotel attack illustrate the need for better tactical information for first responders. This capability replaces the need to carry physical maps that may be out of date. GIS capabilities further provide a means to visually connect different layers of information to improve on-scene situational awareness.

GIS / CADD Request UL	20 kbps
GIS / CADD Request DL	**100 kbps
**file size assumes DWG or similar format and avg sizes	

5.) Blueforce Tracking (BFT)
The location of public safety personnel can be remotely monitored during high risk operations to enhance first responder safety. Fire and police services have been interested in this technology for several years and recent developments in the defense industry now make public safety availability likely in the immediate future. Broadband technology will allow blue force tracking solutions to be available when necessary. Since first responders are typically responding to unplanned incidents there is limited time to deploy ad-hoc or temporary networks for blue force tracking applications. BFT can be used to monitor firefighter and police officer location, and vital signs. Body worn video can be deployed to provide tactical and situational information to field and command personnel.

BFT Data Transfer UL	*25 kbps
BFT Data Transfer DL	*25 kbps
*Assumes polling at 5 second intervals	

6.) Automatic Vehicle Location (AVL)
Real time location and status of public safety agency vehicles can be wirelessly transmitted to the dispatch center, allowing the dispatcher to more effectively deploy the fleet, enhancing command and control and improving efficiency.

Data Transaction UL	40 kbps
Data Transaction DL	**60 kbps
** Estimated average transactions with 5 and 30 sec poll rates	

7.) Supervisory Field Access to **CAD and RMS Data**
Public safety supervisors need the capability to monitor personnel and incident activity. Monitoring Computer Aided Dispatch and Records Management Systems wirelessly allows field supervisors enhanced situational awareness and allows field units to react rapidly changing conditions. Although this capability has existed for several years utilizing existing data networks, the functionality has been limited by the lack of sufficient bandwidth. Supervisors are limited to text updates and as more users respond to the incident system response times deteriorate. Users are also limited to text based searches of internal databases and have no access to the internet or web based applications. Broadband connectivity will allow supervisors to search multiple databases simultaneously and receive interactive feedback to allow for further refinement of their search parameters. Secure broadband communications will also allow for access to external databases that would otherwise be restricted for security reasons. Narrowband or even high capacity channelized data systems do not have the bandwidth to sustain

multiple users accessing large amounts of information in a concentrated area. This capability was successfully used in the “Miracle on the Hudson” plane crash in January 2009 when NYPD Special Operations Division (SOD) field supervisors monitored CAD data in real time over the NYCWIN network, thereby eliminating the need for constant dispatcher updates.

Data Transaction UL	20 kbps
Data Transaction DL	**22 kbps
Data Trans. + photo/GIS UL	**40 kbps
** Estimated average transactions based on similar NYCWiN traffic	

8.) Real Time Field Supervision

The capability for Field Supervisors to monitor the location and status of mobile units assigned to them without dispatcher assistance. Utilizing AVL and GIS capabilities, field supervisors can view their area of responsibility and “see” the units on a map. AVL will allow the supervisors to select a unit’s icon and instantly see status, assignment, duration of service and other related information.

Data Transaction UL	20 kbps
Data Transaction DL	**25 kbps
** Estimated average transactions with 5 and 30 sec poll rates	

9.) Exchange of Broadband Data in the Field

Mobile units operating in the field can exchange data regarding an incident without dispatcher intervention, decongesting voice channels and allowing dispatchers to process incoming job assignments more efficiently. This data may include photos, video or audio files. This capability aids in the positive field identification of suspects, weapons, stolen items or other evidence. The exchange of data in real time between geographically separated team members improves officer productivity and enhances the investigatory process by enabling crimes to be solved faster and more effectively.

10.) Wireless Call Boxes

Emergency (911) call boxes can be installed in any location within the wireless network coverage footprint, regardless of the availability of wire line connectivity.

VOIP Call DL	20 kbps
VOIP Call UL	20 kbps

Police Specific Applications

1.) Mobile Crime Scene Units (Detective Division)
Crime scene investigation involves the gathering of evidence and subsequent analysis by specialists at a centralized location. Specially equipped vans staffed by detectives can respond to a crime scene to gather and analyze evidence. Immediate access to critical information will provide invaluable assistance to investigators and lead to more timely apprehensions. The information must be gathered and analyzed quickly and effectively, in real-time. Broadband connectivity will allow immediate analysis of evidence saving valuable time. Crime scene photos, video, forensic data and other information gathered at the scene can be instantly transmitted to the Real Time Crime Center or crime lab for detailed analysis.

2.) Automated License Plate Recognition (LPR)
Public Safety and government vehicles equipped with Automatic License Plate Recognition systems can scan hundreds of license plates within minutes, sweeping an area for wanted or stolen vehicles with little operator intervention. Additionally, LPR systems can be used to enhance officer safety by transmitting real-time vehicle stop information to the dispatcher and automated database inquiries for car-stops. Broadband connectivity will allow agencies to quickly deploy fixed LPR systems to monitor traffic in and out of a defined area or along major roads for major incidents and temporary security operations.

License Plate Reader UL	256 kbps
License Plate Reader DL	22 kbps

3.) Mobile or Handheld Summons Issuance
Traffic Enforcement Agents and police officers can issue summonses using hand held and mobile ticket writers connected to the broadband network. These devices can access Department of Motor Vehicles (DMV), National Crime Information Center (NCIC), National Law Enforcement Telecommunications System (NLETS), and agency databases in real time, thereby alerting the agent or police officer to a wanted or stolen vehicle, and verify the accuracy of the data entered. Photos and GIS data can be combined with the

violation for accuracy and real-time location information. Wanted vehicles can be cross-referenced in real-time with violation information to support detectives during an investigation; an activity that normally would take several days can be accomplished in minutes.

Data Transaction UL	20 kbps
Data Transaction DL	20 kbps
Data Trans. + photo/GIS UL	40 kbps

4.) Chemical, Biological, Radiological, Nuclear and Explosive Detection Devices (CBRNE)

Portable, fixed and deployable sensors designed to detect Nuclear, Biological and Chemical agents can be deployed almost immediately or strategically placed in high threat areas for remote monitoring through the broadband network. Wireless connectivity allows the sensors to be relocated rapidly if necessary without regard to wire line connectivity availability, should the threat location change. The City of New York has been testing devices over the NYCWiN network with great success. In the event of a CBRNE incident the information can be monitored at remote locations reducing risk of further exposure to the threat. The devices can also be deployed at major events such as sporting events, concerts and other large gatherings without consideration for wired data connections.

Data Transaction UL	20 kbps
Data Transaction DL	20 kbps

5.) Real Time Crime Center Wireless Connectivity

The NYPD Real Time Crime Center (RTCC) allows investigators to gather, correlate and analyze data from numerous sources at speeds previously unheard of in law enforcement. The RTCC allows Officers in the field to transmit photos or video directly to the RTCC from handheld devices for analysis. Key components of the RTCC include a data warehouse, data analysis software and a video wall. Using these tools, Police Officers quickly analyze data from numerous data bases and establish relationships that otherwise are not immediately apparent. Prior to the establishment of the Real Time Crime Center, data now correlated literally within minutes could have taken days or weeks.

Broadband Wireless connectivity plays an integral role in the operation of the NYPD Real Time Crime Center. The ability to transmit photos and video clips from the field in real time, or from the RTCC to the field, greatly accelerates the investigative process. Currently the NYPD utilizes a commercial wireless provider to supply the broadband wireless connectivity. The implementation of a Public Safety 700 MHz. broadband network would provide a cost savings to the NYPD by eliminating the expense of monthly recurring charges. The 700 MHz. band provides greater in building penetration than the 2.5GHz. NYCWIN network which is used primarily for vehicle based applications. In addition a public safety 700 MHz. broadband wireless network would allow public safety agencies to purchase relatively low cost handheld devices similar to those used in commercial wireless networks.

6.) Transmission of Video from Aviation Units to Terrestrial Mobile Units.
Current technology limits the ability of aviation units (helicopters) to deliver video to multiple terrestrial mobile units. Utilizing wireless broadband connectivity will allow the video feeds transmitted from aviation to be distributed to mobile command posts and responding units. The existing equipment requires the mobile command post to be stationary and erect a receiver directed towards the helicopter. Sufficient bandwidth is required to allow for video distribution to multiple units at the scene, responding to the scene and at remote locations. Broadband wireless connectivity will allow the video to be transmitted to a central repository and re-transmitted to any mobile or fixed unit within the coverage footprint of the broadband wireless network.

Incident Video Viewing DL	1150 kbps
Incident Video Viewing UL	28 kbps

7.) Photo ID
Field Officers can verify the identity of suspects or other individuals being detained, particularly those with common names or without valid identification. This capability enables Officers to detain or release individuals with a much higher degree of accuracy.

Photo ID DL	40 kbps
Photo ID UL	60 kbps

8.) Field Officer Direct Access to Remote Databases
Field Officers can verify the validity of license data without dispatcher intervention. (DMV records, Pistol License data, Peddler Permits etc.)

* estimates based on file sizes from NYPD mobile data photo pilot	

9.) Gunshot Detection

Gunshot detection system have been shown to reduce incidents of gunfire in targeted areas, assist investigators with timely and accurate information and provide invaluable evidence for court cases. The systems rely on strategically placed sensors and some form of line of sight connectivity. In urban areas placement of these sensors can be difficult if not impossible using line of sight communications. Connecting the sensors via broadband affords the user optimal placement options, rapid deployment and critical file transfer capabilities. The incident information and audio files can be instantly sent to the communications center and units in the vicinity to enhance response to gunshot incidents. Additionally, the sensors can be relocated as needed without wire line installation considerations or constraints.

Incident and Audio Transfer UL	*65 kbps
Incident Transfer to Unit DL	80 kbps
Data Transaction Text Only DL	25 kbps

10.) Photo and Video Distribution

In an investigation of a crime or missing person the first 30 to 60 minutes are critical to the resolution process. Photos or video of missing or wanted individuals can be distributed to mobile field units in real time improving the likelihood of a successful outcome. (Amber Alert Wanted Persons etc.) The process, if done manually, may take several hours to initiate and distribute the information to the field. Broadband capability will greatly enhance response to these types of incidents.

11.) Maritime Surveillance and Monitoring

Port Security is a priority as part of the nation's efforts to protect critical infrastructure and prevent acts of terror. There is the potential for weapons and explosives to enter coastal ports on cargo ships. DHS has stepped up their inspection efforts and port monitoring, however the deployment of a wireless sensor network would greatly enhance the security of our ports. Cargo manifests, ship information and travel itineraries can be made available in real time to Coast Guard and local law enforcement to enhance investigations. Remote sensors can be deployed in strategic locations to assist in early detection of dangerous cargo. These types of systems can only be deployed if sufficient bandwidth is available to allow for exchange of critical information and the monitoring of remote sensors.

Fire Service Applications

1.) Electronic Command Boards (ECB)

The Fire Department has developed an Electronic Command Board to support fireground operations at the scene of an incident. The ECB allows the Fire Chiefs at the scene of a fire to exchange critical information and provide live updates to the Operations Center. The ECB requires a broadband application to transfer information in a timely fashion. At the scene of many large scale incidents commercial wireless networks are often overloaded and cannot provide the necessary bandwidth for ECB to operate properly. The ECB requires a broadband connection for optimum operation. Fire Chiefs at the incident scene can track responding units and transmit this information to Fire headquarters in real time enhancing Command and Control capabilities.

Data Transaction UL	40 kbps
Data Transaction DL	120 kbps

2.) Wireless Access to Floor Plans, Drawings and 3D Graphical Displays

Responding units and commanders require access to building floor plans, schematic diagrams and 3D graphical displays to enhance situational awareness. For Fire Chiefs at the scene of a major incident this capability allows incident commanders to make informed decisions regarding resource deployment thereby enhancing Firefighter and citizen safety. Early transfer of critical information will allow firefighters to approach the incident tactically thereby reducing initial critical response times.

Access included in Building Department records, including the presence and location of potentially hazardous materials within the incident perimeter enhances situational awareness and Firefighter safety.

Data file transfer CADD/GIS DL	500 kbps
Data file transfer CADD/GIS UL	50 kbps

EMS Applications

1.) Automatic Vehicle Location (AVL) Integrated CAD

The location and current status of all ambulances can be wirelessly fed into the EMS Computer Aided Dispatch computer. The EMS CAD computer uses this information to make recommendations to the EMS dispatcher for the next assignment. Implementation of this type of system can result in a significant reduction in response time.

Data Transaction UL	40 kbps
Data Transaction DL	**60 kbps
Data Transaction for Routing	120 kbps

2.) Patient Tracking

Family members routinely inquire about the location of their sick or injured relatives. Access to a broadband wireless network allows EMS workers to accurately track patients and provide this information to their family members in near real time, increasing productivity and reducing patient tracking errors.

Data Transaction UL	30 kbps
Data Transaction DL	50 kbps

3.) Real Time Transmission of Medical Data

Medical data such as ECGs, photos or videos of injuries and patient history can be wirelessly transmitted to receiving hospitals in advance of a patient's arrival permitting Emergency Room staff to assemble the appropriate personnel and equipment in advance. Advances in mobile telemedicine equipment enhance the initial diagnosis and field treatment of critically injured or sick patients. Information in the form of broadband data can be exchanged between the on board Emergency Medical Technicians and the hospital medical staff to assist in patient treatment during transport. This data may include photos, video, video conferencing and other forms of medical information.

Governmental Non First Responder Agency Applications

The Public Safety Broadband Wireless Network will support QOS and priority. These mechanisms will allow other municipal lower priority users to access network. Allowing non emergency municipal agencies network access improves overall spectrum efficiency. A few examples are listed below:

Sanitation Department Applications

1.) Automatic Vehicle Location (AVL) and Vehicle Monitoring

Real time location and status of Sanitation Department vehicles is wirelessly transmitted to the Sanitation Department dispatch center, allowing the dispatcher to more effectively deploy the vehicle fleet, enhancing command and control. The AVL application also monitors the status and health of the sanitation vehicles by connecting to the data interface.

Remote vehicle sensors installed in Department of Sanitation vehicles wirelessly transmit vehicle status data to the Department of Sanitation dispatch center. These sensors monitor vehicle health as well as mission status (truck full, sand or salt released, at vehicle location etc.). This data is particularly effective in managing fleet resources during snow removal operations, which are the responsibility of the Sanitation Department in NYC.

Supervisory Inquiries UL	60 kbps
Supervisory Inquiries DL	100 kbps
Based on NYCWiN data	

Department of Transportation Applications

1.) Wireless Traffic Signal Control

The Department of Transportation is installing new traffic controllers equipped with broadband wireless modems that communicate with the Traffic Control Center in real time, allowing for the wireless control of traffic signals and eliminating the need for wire line backhaul. New traffic signals can be installed in any location within the wireless network footprint without regard for wire line availability, reducing installation time and expense while eliminating recurring (leased wire line) costs. The wireless modems will also allow DOT to implement ITS enhancements such as emergency vehicle priority access, route information and messaging, and traffic management.

Municipal Government and Critical Infrastructure Applications

Sharing the public safety network with other governmental entities on a priority basis enhances and increases public safety agency's return on investment while simultaneously satisfying the original intent of the public safety broadband wireless network to provide ubiquitous national data coverage for first responders. A few examples are cited below.

1.) Wireless Meter Reading
Water, electric and gas meters read remotely taking advantage of the broadband wireless network and/or its backhaul infrastructure to improve accuracy and reduce labor costs.

Data Transaction UL	25 kbps
Data Transaction DL	20 kbps

2.) Wireless Leak Detectors
Water and gas leak detectors connected to the broadband wireless network can be read remotely in real time. These detectors can be installed in any location within the wireless network footprint without regard to wire line availability; reducing installation time and expense and eliminating recurring (leased wire line) costs.

Data Transaction UL	20 kbps
Data Transaction DL	25 kbps

3.) Bus Locator (AVL)
The real time location and status of municipal buses can be wirelessly transmitted to the bus dispatch center, allowing the dispatcher to more effectively deploy the vehicle fleet, enhancing command and control and providing improved service to the public. In addition, it is possible to monitor engine parameters, and emergency requests from the driver in real time, or an alert basis.

Section Seven
Conclusion

Real time access to broadband data improves the efficiency of public safety personnel by giving them the tools they need to perform their job. The delivery of broadband data to field personnel requires access to a wireless broadband network. The FCC has taken the first steps by allocating spectrum in the 700 MHz band to Public Safety for this purpose. Unfortunately, the spectrum allocation will not meet future public safety demands. However, an adjacent spectrum block, the "D Block" has yet to be auctioned. We appeal to Congress to relieve the Commission of their legal obligation to auction the D Block and we implore Congress to direct the Commission to assign the D Block to public safety.

This document has defined some of the broadband applications public safety can benefit from with the assignment of the D block spectrum, and has demonstrated that the current assignment of two 5MHz channels is insufficient for the task. Although technology advancements will improve network capacity (throughput), they will not outpace demand for broadband spectrum. LTE is a very spectrum efficient technology. Improvements in capacity beyond LTE are possible but the physical limit of the radio channel (Shannon Boundary) will limit the magnitude of these improvements.

A unique opportunity exists to change the paradigm of public safety communications where multiple frequency bands and incompatible technologies create obstacles to interoperability and perpetuate inefficiency. We urge Congress to take the first steps to allow public safety to learn from the mistakes of the past and plan for a future in which wireless broadband networks deployed on a common frequency band using a common technology platform provide public safety with the tools they need for the twenty first century.

We endorse the vision of a broadband public safety interoperable data and mission critical voice network listed as a national priority in the September 2009 Draft National Broadband Plan[9], and in NTIA's "Executive Branch Views on Public Safety, Homeland Security and Cyber Security Elements of a National Broadband Plan"[10]. We believe that in order to achieve this vision, Congress should direct the FCC to forgo a second D Block auction and direct the Commission to assign the D block to public safety.

APPENDIX A

Appendix A is an excerpt from New York City's recent Comments filed with the Commission. It is included here to underscore our major points and provide broadband throughput analysis data.

Current and Anticipated Needs of the Public Safety Community for Mobile Wireless Broadband Networks and Applications.

New York City is closely monitoring the evolution of Long Term Evolution ("LTE") technology as it relates to both mission critical data and voice applications including duplex phone calls, push to talk, instant messaging and broadcast video. Broadband technologies are developing at a rapid pace and the possibility of LTE supporting "push-to-talk" voice communications must be investigated as an alternative to narrowband technology. The lessons to be learned from past experience is that increasing channel size (broad-banding) rather than reducing channel size (narrow-banding) leads to more efficient use of scarce spectral resources. New York City understands that the LTE standards for voice have not been fully developed and that initial forays into broadband voice communications may be a few years away, however the Commission should act now to ensure that sufficient spectrum is available and that public safety standards are developed for this technology to evolve.

Anticipated Broadband Traffic and Capacity Requirements

Using New York City's experience in building the NYC Wireless Network (NYCWiN) as a basis for analysis our team examined the impact that broadband systems may have in the future operations of the public safety. We have collected important data points by gathering application usage from the NYCWiN network in order to provide real-world operational and performance data for the Commission's discussion on broadband usage. First, the NYCWiN 2.5 GHz broadband system provided a basis to characterize the various types of broadband applications that are in use today by the NYC public safety and public sector users. These applications and associated data rates are seen in table 1 below.

Data Rates	Download (Kbps)	Upload (kbps)
Incident Video upload	12	647
AVL Monitoring	51	4
Website Viewing	90	5
SFTP Transfer	93	92
Field Video Viewing	1150	28
Mobile Audio & Video upload	19	96

Table 1 - Typical Data Rates Derived from NYCWiN

The analysis focuses on two very important areas of consideration necessary in understanding the future needs for spectrum for New York City. First we examined the impact of secure broadband applications and the relation to bandwidth to support these applications. As has been discussed throughout the proceeding related to the 700 MHz spectrum, public safety has a critical need to improve daily operations through the use of mobile and fixed applications and technology.

However, it is important to understand the public safety systems must be designed to function outside of the accepted norm for everyday operations to best understand the bandwidth requirements for first responders. As we have seen many times, commercial systems have shown the greatest amount of stress during major City disasters and special events such as:

- September 11th attacks in New York and the Pentagon
- American Airlines Flight 587: 11-12-01
- Staten Island Refinery Explosions: 2-21-03
- Staten Island Ferry Crash: 10-15-03
- Midtown Building Collapse: 7-10-06
- Cory Lidle Plane Crash: 10-11-06
- Midtown Steam Pipe Explosion: 7-18-07
- Multiple Crane Collapses: March and May 2008
- Miracle on the Hudson: 1-15-09
- Helicopter/Plane Crash on the Hudson 8-8-09
- Annual and Special Events (i.e. NY Yankees Parade: 11-6-09)
-

In many of these instances the commercial networks were overloaded with users confined to a small area rendering the networks unusable. In other cases the networks were rendered inoperable due to the lack of sufficient battery back-up or emergency power. These, as well as other real life examples, demonstrate that commercial networks are not designed to function under the stress of critical incidents and when needed the most, cannot perform as required.

We intend to demonstrate, through our analysis, that first responder and public safety services require significantly more bandwidth and capabilities than is presently allocated to public safety in the 10MHz allocation in the 763-768/793-798 MHz band segment. The City also believes that the most effective approach to a broadband public safety network necessitates the allocation of sufficient spectrum to satisfy current and future needs of First Responders.

Normal Operations Scenario

Using real data from our analysis of NYCWiN applications, and using the projected target numbers for the desired adoption of a broadband network by public safety users in New York City; we examined the impact over time for system bandwidth usage as compared to available system capacity. We used models that are similar to in structure those models used by commercial broadband providers in analysis of their capacity needs, but adapted with assumptions appropriate for public safety usage. Using real world experience and our judgment based on our knowledge of the operational goals of Public Safety and other agency plans for broadband we have defined four classes of applications; vehicle MDT installations, Automated License Plate Recognition (ALPR), operational video, and personnel handheld devices. The model assumes a conservative 5% per year increase in the per user bandwidth requirement for both the MDT and handheld users based on current trends in technology growth and additional system capabilities.

Commercial networks generally use a 5% to 10% available user to active user ratio. In simple terms, at 5% usage the assumption is that 1 out of 20 users will be using the system at any one time. For the public safety environment we determined that the commercial carrier formula is not applicable based on a number of factors. We must assume that these devices are used in the day-to-day operations of a majority of system users and are typically reused by each on-duty shift. The number is not likely to be applicable in heavy daytime operation hours for operational vehicles and handheld personal devices. Additionally, the commercial carrier assumption of 5% to 10% of registered users cannot be applied during events such as parades, demonstrations and other large deployments of public safety personnel. As such, a 25% available to active ratio was used for mobile data terminals in vehicles and a 100% ratio was used for machine-to-machine users such as license plate readers.

Normal Operations Model

Using a simple model based on accepted commercial analysis techniques, we examined scenarios that consider the impact of a 12 year program maturation period for a secure broadband network deployed in New York City at 700 MHz. The model network deployment assumes a comparable street-level coverage design to NYCWiN for the 5 boroughs within New York City and uses the known capacity and bandwidth performance of LTE standard equipment as of this writing. The demand model starts with 1,000 vehicle deployments, 40 LPR units, 100 mobile video assets, and 1,000 mobile handheld users. Over the 12 year period the users adopt the network using an "s-curve" model to a final count of 10,000 vehicles, 1,200 LPR units, 2,000 video assets, and 25,000 mobile handheld users. These numbers come from a conservative analysis of anticipated user demand for a secure network of this type by public safety users in New York City, however the potential if expanded beyond local jurisdictions to State and federal entities could easily exceed 100,000 end user devices.

The demand model is then compared against different levels of aggregate capacity that would be available based on different amounts of spectrum. In the case of a 10 MHz spectrum allocation, as illustrated by the graph in Figure 2, the conservative adoption of a 700 MHz network by agencies would result in the UL demand reaching 75% in year 5 and 100% in year 6; while the DL demand reaches 75% in year 7 and 100% in year 9. The model uses very conservative usage assumptions and bandwidth per user requirements and it is anticipated that it is likely these estimates may be low as secure broadband data access becomes an integral part of everyday operations. The commercial industry equivalent to the plausible underestimation of usage comes in the form of the stress placed on commercial carrier networks by smart phones like the I Phone from Apple. These phones have placed significant stress on the capacity of commercial network data services because of the accelerated adoption of new applications and utilization of bandwidth for these new applications.

The 20 MHz LTE analysis uses the same demand assumptions but increases the available aggregate bandwidth as a result of increasing the spectrum available to the Public Safety network from 10 MHz to 20 MHz. The analysis found that the uplink capacity of the network still reaches the 75% at year 8 but never reaches the 100% mark over the 12 year period. The DL system capacity stays below 75% over the entire period of the 12 years, but it does reach a level of >50% as early as 7 years. It is important to note that just a single major incident will require bandwidth well beyond the everyday operational capacity of the network and sufficient reserve bandwidth must be available to ensure proper operational support during a major incident. We have included a parallel analysis of a major incident in figures 3 and 4 on the following pages.

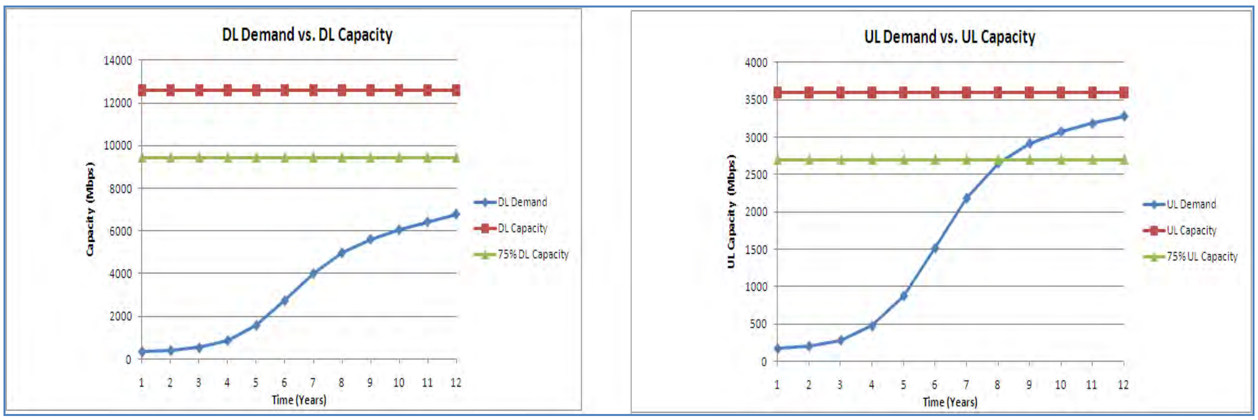

Figure 4 - 20 MHz LTE Capacity Model Graphs

Normal Operations with Voice Application

While the previous section considered only data applications to estimate the total bandwidth demand, in this section we add mobile, enterprise-class Voice as an application and analyzed its impact on overall bandwidth demand. (As standards have yet to be defined for mission critical voice for LTE, we have focused this analysis on non-mission critical use for which reasonable bandwidth estimates can be made) We start with 1000 voice users increasing to 25,000 users at the end of 12 year program maturity period. Voice is a relatively low bandwidth application requiring only about 25 Kbps of bandwidth on both the downlink and the uplink. Current industry estimates of LTE voice capacity are ~160 and ~ 320 simultaneous voice calls in 10 MHz and 20 MHz bandwidth respectively, assuming the entire capacity is dedicated to voice. Under the current assumption of a street-level coverage design of 200, 3-sectored sites, this translates to ~96,000 and ~192,000 total voice users in 10 MHz and 20 MHz bandwidth respectively.

Our assumption of maximum of 25,000 users accounts for only ~26% (~13%) of the total voice capacity if all the 10 MHz (20 MHz) capacity were to be dedicated for voice use. This shows that with the number of assumed voice users, there is still considerable capacity available in the network for other data applications. The charts below show the total demand, including voice, versus available capacity in the network for the two cases of 10 MHz and 20 MHz of bandwidth.

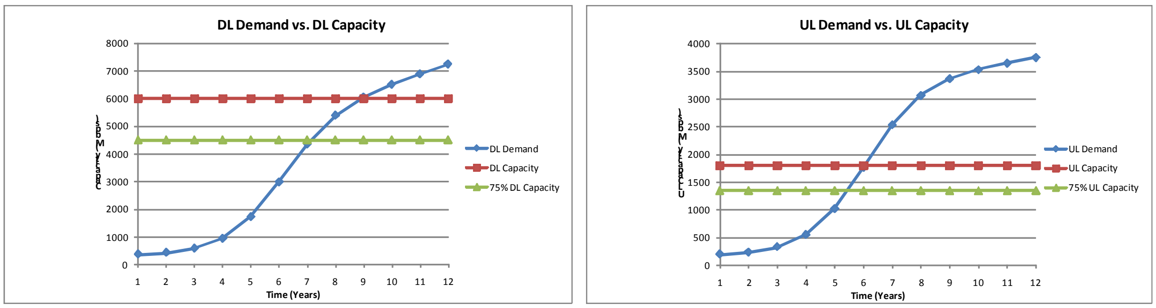

Figure 5- 10 MHz LTE Model Capacity Graphs with Voice

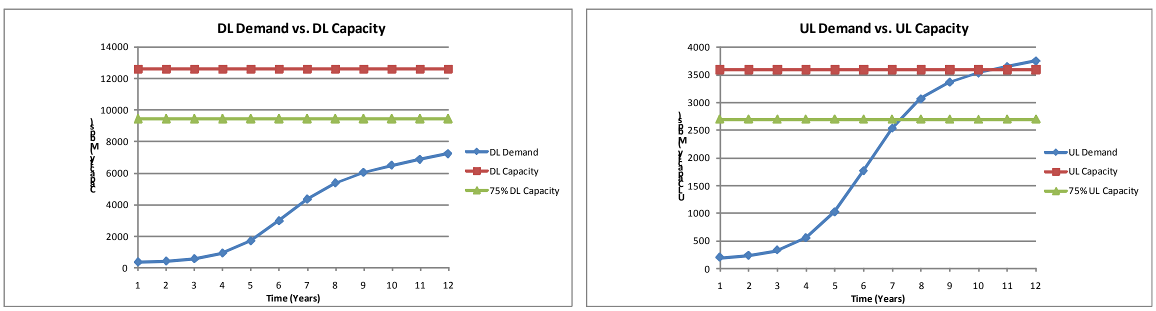

Figure 6- 20 MHz LTE Model Capacity Graphs with Voice

Comparing these charts with the case without voice, we notice a small impact on capacity. For the 10 MHz case, threshold of 75% downlink capacity is exceeded at the end of 7 year instead of 7.5 year without voice, The Tables below illustrates the capacity impact of adding voice for both the 10 MHz and the 20 MHz cases.

75% Capacity Exceeded	With Voice	Without Voice
Downlink	7 years	7.5 years
Uplink	5.5 years	5.8 years

Table 2 - Capacity with and without Voice with 10 MHz LTE Bandwidth

75% Capacity Exceeded	With Voice	Without Voice
Downlink	> 12 years	>12 years
Uplink	7.1 years	8 years

Table 3 - Capacity with and without Voice with 20 MHz LTE Bandwidth

Although the impact of adding voice to the overall capacity is small, this is true only for the number of voice users assumed in this model. If the number of users becomes significantly higher, that would result in a considerable impact on available capacity. Likewise, the model does not take into account the potential impacts on data traffic associated with the yet-to-be-defined implementation of VoIP on LTE. If, for example, the real time nature of VoIP traffic is supported by dedicated channels or bandwidth, the effective bandwidth available to other data traffic could be reduced beyond the linear model assumed in this analysis.

Critical Incident Bandwidth Requirements

While a public safety broadband wireless network provides valuable services to the public safety personnel in the execution of their day-to-day mission operations, it is during an emergency incident brought about by natural or man-made disasters that the potential of a broadband network is truly and fully realized. Public safety networks must be designed and built to meet the most stringent requirements for reliability, availability, quality of service, and security. An important aspect of public safety broadband networks that requires careful consideration is their engineered capacity, and that is strictly a function of the total amount of spectrum available for public safety use. Although the networks can be engineered and hardened to highest standards of reliability and availability, that is meaningful only if there is enough capacity available in the sites serving an incident scene to meet the communication requirements of hundreds, if not thousands, of first responders. A capacity shortfall during a major incident scene would result in blocked and delayed calls, significantly hampering the efforts of public safety personnel to save and protect lives and property. Since an incident can strike without warning at anytime and anywhere in the jurisdictional area of a network, it is imperative that all the sites in the network be provisioned with enough capacity to handle the worst case scenario that would unfold during an emergency situation.

We must assume that a major incident such as the September 11th terrorist attacks on the World Trade Center, if such an incident were to occur again, will require a large and coordinated response by federal, state and local public safety First Responders and support personnel. The purpose of the National Broadband Network is to provide high-speed interoperable data and voice communications for First Responders. The network, under normal circumstances, will be used by the local or regional agencies to conduct day-to-day operations in the conduct of their public safety mission. However, should another terrorist attack of similar proportion occur there will be a large scale response from federal, state and local jurisdictions into the incident area. In the future, when the regional segments of the network are built-out, First Responders and support personnel will be using the network while en-route to the incident and upon arrival at the scene. Because of the dense urban and suburban populations of the greater metropolitan areas there are upwards of 50,000 state and local public safety First Responders in the immediate metropolitan area. In addition, there are many federal agencies that maintain personnel in the area that could potentially respond to a major incident. It is conceivable that the number of active users could increase by approximately 75% if a large response is required.

New York City Critical Incident Response Simulation
In the following section we describe an incident scene in the New York City with the specific objective of estimating how much spectrum is required to adequately meet the communications requirements of First Responder emergency operations.

The incident involves a "dirty bomb" set-off at Pennsylvania Station in Midtown Manhattan. The device was planted in the information and ticket sales area of the Amtrak area and has caused moderate structural damage to the area and has caused secondary damage to the structure above and below Amtrak's Penn Station. The area below the Amtrak section is part of the Long Island Rail Road (LIRR) complex and has damaged passenger corridors and waiting areas. The bomb also damaged the structure above the Amtrak waiting area which is part of the Penn Plaza / Madison Square Garden Complex. Immediately above Penn Station is a large office building that is operating at 75% occupancy.

The "dirty bomb" has released nuclear contaminants throughout the Amtrak and LIRR complexes and into the areas above and below the stations. The bomb also caused fires to break out on all levels including the track levels. The fires are causing a large smoke condition throughout the complex and into the track areas of the LIRR, Amtrak New Jersey Transit, and the New York City Subway. Smoke is also billowing out of the station at the street level exits and blanketing the street area immediately around Penn Station.

Incident Assessment
There are approximately 400 injured passengers on the Amtrak / New Jersey Transit level and 500 injured passengers on the LIRR level, The injuries range from critical and serious near the center of the explosion to minor caused by fleeing passengers and the heavy smoke conditions. There are injuries on three levels of the station and above the station from falling glass and building materials.

The New York City Police Department (NYPD) has initiated a level 4 mobilization setting up command posts in the vicinity of 34th St. and 8th Ave. The FDNY's Command Tactical Vehicle, Mobile Field Communications, and Emergency Medical Field Units are set in the same area. The Office of Emergency Management has set-up their command vehicle on 8th Ave near 34th St. All of the mobile command posts are near each other.

Fire Department of New York City (FDNY) is setting up a hazardous material (HazMat) detoxification / wash-down area on 31st St. and Broadway, while Emergency Medical Services (EMS) has set up their mobile triage vehicles on 31st St. and Broadway.
The Departments of Health and Mental Hygiene and Environmental Protection have responded with their mobile command posts and have placed them in the vicinity of 35th St. and 7th 8th Ave. FDNY will use 34th St. and 8th Avenue for ambulance and bus staging and the NYPD has closed off Broadway, seventh and eighth avenues from 20th St. to 42nd Street.

New York City Transit (NYCT) has been asked to stage busses to begin transporting the injured to area hospitals and has responded with a mobile command center located near the Office of Emergency Management (OEM) command vehicle.

Emergency Response

Because of City's preparedness to handle incidents of this magnitude, there is a swift and coordinated response from a number of different agencies including Police, Fire, Emergency Medical Services, and Office of Emergency Management Services among many others. Each agency, in turn, will respond with several different units trained, equipped, and specialized in handling specific aspects of emergency response. For example, in this particular incident, NYPD will respond with, in addition to patrol vehicles, a number of different specialized units such as Detective Bureau, Intelligence Division, and Mobile Command Posts etc. Table 1 below illustrates the level of effort required to handle a crisis of this magnitude. For each of the major agencies, it lists the different units, the number of units that would be converging at the scene, and typical applications they would be using.

Table 4 - Agency Response

Police Department			
Agency	Qty	Primary Application	Secondary
NYPD Mobile Command Posts Borough and Comm. Div.	2	Requires video from deployed cameras as well as the ability to view video from other sources. Each MCP will deploy a number of wireless cameras and monitor other feeds from other MCPs and agencies. AMTRAK Command Post	1	Video, applications, databases, internet	

Bandwidth Requirements Analysis

We used the model of the expected users, command vehicles and associated applications associated with the response to estimate the total bandwidth demands that would be required during the peak response periods following the incident. We have assumed that the incident area is served by a public safety broadband wireless network that is built using fourth generation Long Term Evolution (LTE) technology and operates in the 700 MHz public safety frequency band.

Table 5 below lists the average capacities available from a single LTE sector using 10 and 20 MHz of spectrum.

Spectrum	Downlink Capacity	Uplink Capacity
10 MHz, (5 MHz Downlink, 5 MHz Uplink)	10 Mbps per sector	3 Mbps per sector
20 MHz, (10 MHz Downlink, 10 MHz Uplink)	21 Mbps per sector	6 Mbps per sector

Table 5 - Spectrum versus Capacity

The aggregate bandwidth requirements of the applications used during the incident can be compared against the available capacity. Estimated bandwidth requirements of typical applications used during at an emergency incident are listed in Table 6.

Application	Downlink Data Rates (Kbps)	Uplink Data Rates (Kbps)
Incident Video Upload	12	647
Field Video	1150	28
Data Access	10	100
CAD Dispatch	50 Kbps	50 Kbps
VoIP	25 Kbps	25 Kbps

Table 6 - Application Data Rates

As illustrated in Table 6, video applications are the most demanding in terms of bandwidth usage. However, it is also a critical application for incident management, sending images in real time from the incident scene to the command and control centers enhancing situational awareness and providing a current and consistent operating picture required for effective and coordinated response. An incident scene will typically have a large number of video cameras streaming information back to the command vehicles present at the scene as well as to the central command and control centers. Command staff personnel from each agency will make extensive use of the video feeds to get a real-time view of rapidly and dynamically changing situation at the incident scene to aid them in their decision making process and to coordinate their response with other agencies.

In the incident scene we have depicted there are 38 simultaneous downlink video streams consuming about 44 Mbps of bandwidth at 1.15 Mbps per video stream. These streams are distributed to the various public safety command vehicles present at the scene. This combined with other applications such as database access, file downloads, telemetry, computer aided dispatch, VoIP results in an aggregate sustained downlink bandwidth requirement of about 60 Mbps.

On the uplink, we have assumed that the agencies will deploy twelve portable or vehicle mounted cameras continuously sending real time images from the incident scene. This utilizes about 9 Mbps of bandwidth on the uplink. Another significant consumer of uplink bandwidth is ambulances sending triage images back to the hospitals to inform them in advance of the nature and seriousness of the injuries. We estimate that EMS will utilize about 2 Mbps of uplink bandwidth. Coupled with uplink usage of other applications, aggregate bandwidth used on the uplink is about 16 Mbps.

The aggregate bandwidth demands in above can be compared against the bandwidth that would be available in an incident scene. Available bandwidth is a function of the number of sectors/sites that would be within range of the incident scene and bandwidth available per sector, as shown in Table 5. Table 7 shows the total aggregate demand at the incident scene and the number of sectors of bandwidth that would be required to fulfill that demand.

Spectrum	Downlink Demand	LTE Sectors Required for DL Demand	Uplink Demand	LTE Sectors Required for UL Demand
10 MHz (5 MHz uplink) (5 MHz downlink)	60 Mbps	6	16 Mbps	6
20 MHz (10 MHz uplink) (10 MHz downlink)	60 Mbps	3	16 Mbps	3

Table 7 - Total Incident Scene Demand

The number of sites that would realistically available to support an incident is a function of the network design and the geographic distribution of the users. In the example provided, given the localized nature of the incident coupled with lower site count due to superior propagation characteristics of the 700 MHz frequency band relative to other higher frequencies such as 2.5 GHz and 1.9 GHz, it is likely that the incident scene would be served by only 3 sectors.

For incident scenario presented and the associated site density, 10 MHz of spectrum will fall considerably short of the required bandwidth demand. 20 MHz of spectrum is barely sufficient to meet the projected demand. We realize, however, that the incident we have utilized in our model represents an extreme case but it is entirely within the realm of possible threats for a large metropolitan city like New York. To meet the extraordinary demands that are placed on a network during emergency situations, we strongly believe that 20 MHz of spectrum is needed in order to prevent the network from being saturated and to continue providing reliable service.

Incident Scene Operations

Incident Scene Response Units	Qty	Primary Application	Secondary Application	DL Data Kbps	UL Data Kbps
Mobile Command Posts	2	Receive 4 video feeds	CAD, internet, incident mgmt, VoIP	9700	442

Table 8 Incident Scene Operations

City's Response to Commission Questions Regarding Operational Requirements

The FCC has suggested three categories of operational conditions relative to demand; critical, medium and low. For the purposes of this filing we will define the three categories as follows:

> Critical – Network usage during a major incident(s) supporting a large scale response to a catastrophic event such as a bombing or natural disaster. This type of incident will initiate responses from local, federal and mutual aid agencies for initial response, rescue and recovery. Using prior incidents as a model the City can expect the number of first responders to grow exponentially as the incident progresses through its various stages and the network utilization to fluctuate between periods of extreme (>75%) utilization, heavy utilization (>50%) and medium utilization (<50%).
>
> Medium – We have assumed that medium usage refers to normal operations during the primary work hours of a public safety agency such as the police department or the fire department. Based on staffing levels the time period for medium usage will span from early morning rush hour for both vehicular traffic and public transportation, through the normal and extended workday, the end of the school day and evening hours until midnight. This period of time from approximately 5:30 AM to 12:00 AM comprises the majority workload of the New York City Police Department. This model also takes into consideration typical tourist and commuter workforce traffic travelling into and out of the City proper. This model will most likely apply to the Fire Department, specifically with regard to Emergency Medical incidents responded to by emergency medical personnel and firefighters.
>
> Low – We assume that the low usage period will consist of the period of time after the evening hours and prior to rush hour when staffing and equipment is deployed at lower levels. Typical public safety models assume that these hours are less busy than other periods and staff accordingly, however the typical per unit workload may remain similar to the workload during busy periods due to reduced staffing.

During critical usage periods we anticipate that the network will first be utilized by First Responders to coordinate multi-agency response to the critical incident and exchange critical information relative to the incident response and operational plans. This may include but not be limited to:

- Incident data from 911 calls and first responders
- Information sharing for HAZMAT and environmental information
- Coordination of response for federal and mutual aid responders
- Video from fixed cameras that are adjacent to the incident
- Maps and GIS data relevant to the area
- Personnel and equipment rosters for logistics
- Building or location information
- Executive / managerial teleconferencing
- Personnel and vehicle tracking

- Incident Management / Situational Awareness
- Mass Notifications
- Traffic Control and Traffic Advisories
- Download and consolidation of surveillance data for forensic analysis

As described earlier we believe that the type of traffic will constantly fluctuate however the usage will remain high during the initial response period. Depending on the severity the initial response may last upwards of 7 to 10 days as the various first responders arrive at the incident scene. The type of network usage will change based on the stage of the incident response. We must assume that the network will be utilized at approximately 75% of capacity for the first stage of response. The network must support the first responders throughout the period of initial response to the incident through the remaining stages of rescue and recovery.

As evidenced during the September 11th terrorist attacks the initial response was tremendous and the logistics aspect was primarily carried out through a manpower intensive effort. Not only were commercial network services overwhelmed at all levels, their infrastructure was severely damaged and ineffective. Public safety responders did not have a broadband wireless networks to supplement the coordination of the massive response effort and relied on inefficient forms of communications for such a complex event.

It must be noted that during this type of incident the City's first responder agencies must also serve the entire City and not just the area of the incident. In a City as large as New York an incident can occur in a small area with a dense population and still only involve a small percentage of the City's area.

For medium theater operations we have assumed the model of normal daily operations of the City's First Responders. In this category public safety will utilize applications designed for routine business processes. The Fire Department's typical usage will consist of dispatch information for fire and medical incidents that will require broadband communications to transfer patient data, location history and HAZMAT information, building plans and maps, driving directions, patient telemetry, AVL and telematics data and other incident related information. Prior to the adoption of NYCWiN none of this information was available to responding units with the exception of on-scene patient telemetry for EMS. As the agencies begin implementing new technology the utilization demand will rise, primarily driven by many factors; new capabilities, features and functions of systems due to the availability of the broadband network and additional bandwidth requirements as more data intensive applications are implemented. For example; the ability to quickly and efficiently transmit patient data, photos and video of patient's injuries, and bio-metric information to a physician and subsequently allow the hospital staff to assist in field treatment via video teleconferencing will provide tremendous benefit to the citizen's of New York City.

The Police Department will soon have the capability to download photos within seconds from their criminal history databases along with other critical information that will support the investigatory process in the field thus saving valuable processing time. The ability to scan bar-coded documents for traffic violations will not only save time and produce more accurate citations, it will also increase officer safety. Automated and bundled transactions will help the officer make sound decisions and alert him/her of potentially dangerous conditions. These capabilities are not available with today's 25 KHz channelized systems. Real-time data collection will create new capabilities for investigators and counter-terrorism personnel by moving data from the field to the data warehouse as fast as it is collected for critical analysis. Scanning a driver's license will provide the officer with the appropriate information within a fraction of the time previously required to type or call in the information request. The database query will return a photo in addition to the standard DMV and warrant information, helping the officer confirm the identity of the person stopped for the violation. These and many more applications will make first responders more productive and effective. But these applications require an appropriate allocation of spectrum and bandwidth to perform as specified under these normal operating conditions.

Low theater operations do not necessarily reduce the bandwidth requirements due to lower staffing or reduced activity. Individual applications will still require sufficient bandwidth to operate efficiently. However, these periods of lower activity offer opportunities for agencies to update their mobile applications and equipment with security patches, new applications and data. The mobile and portable devices and applications should be afforded the same maintenance features benefits derived from a wired network or a commercial cellular network. Updates, new applications and patches should be pushed out from a central source to the edge devices to keep the users and devices in the field, rather than ferrying devices to depots for software updates. Applying the right design parameters to the network and applications will allow for the efficient maintenance of the devices, applications and data ensuring that the mobile workforce is truly mobile.

No matter how carefully bandwidth planning is done on any type of secure public safety wireless network, the network will eventually be placed in a position of stress due to a major incident or an unplanned increase in utilization. There is not enough spectrum available to provide the necessary overhead to assure that bandwidth will be available during critical incidents where users require immediate and high priority access. It must be assumed that utilization will be higher in certain operational scenarios. Once broadband data systems become widely adopted by public safety it is highly probable, based on analogies to commercial systems, public safety networks will be extremely stressed during events similar to September 11th in New York and July 7th in London. During events such as these usage will dramatically increase, and intelligent mechanisms to handle bandwidth must be in place well before the occurrence of a large scale emergency of this type.

In our bandwidth analysis of the incident scene we discussed the various impacts of applications on bandwidth availability during emergencies. It is clear from our analysis that in scenarios where 20 MHz of spectrum is available to public safety the system will be "stressed" during periods where important characteristics of a network need to exist above and beyond what is available commercially. A public safety system must have built-in mechanisms that support Quality of Service (QoS) prioritized by both applications (voice, video, data, etc.) and by the role of the user based on the operational command structure. Next generation wireless technologies such as LTE have included these mechanisms as part of their adopted standards, however the configuration of these controls must be carefully implemented in any network supporting public safety users. It is highly unlikely that commercial carriers will break with their tradition of "best efforts" delivery and offer guaranteed message delivery and bandwidth allocation. Based on the quantity of users they must support it will be difficult to provide priority services to a small number of users when the demand will be so great from the users at large.

New York City is learning valuable lessons from our implementation of the NYCWiN program on how to deploy and operate applications on a broadband network to ensure that the available bandwidth is efficiently and effectively used in high stress utilization conditions. Application planning must include such concepts as intelligent distribution of data based on role, location, and need utilizing prioritized push technologies to control of information flow during peak and stressed network conditions.

Report for the TETRA Association

Public safety mobile broadband and spectrum needs

Final report

1 Executive summary

This is the final report of a study conducted by Analysys Mason Limited ('Analysys Mason') for the TETRA Association, to undertake a review of future mobile broadband needs for public safety mobile communications, and how these needs might be addressed.

For the purposes of this report, the term 'public safety' is assumed to comprise primarily police, fire and ambulance services, although the requirements are also considered to be applicable in a wider Public Protection and Disaster Relief (PPDR) context.

The majority of public safety users in Europe currently use dedicated radio networks for their mobile communications that have been designed specifically to meet their needs, typically using digital mobile communications technologies such as TETRA or TETRAPOL and operating in spectrum in the 380–400 MHz band. These networks offer a range of low rate data services, but the speed and capacity that is available within those networks limits more widespread use of higher-speed data applications.

In line with societal trends for access to information on the move, public safety operations are becoming increasingly information-driven, requiring access to a wider range of wideband and broadband applications. These range from high-quality imaging to uploading and downloading of large data files, and real-time video.

Given the limitations in capacity of existing dedicated networks to deliver mobile broadband services, it is considered likely that a new generation of solution will be required across Europe in the next five to ten years, to meet future public safety user demands. This new solution, if delivered using new dedicated mobile broadband networks that are designed to meet public safety requirements, will require additional spectrum to deliver the services required.

In order to define the benefits of the development of a new generation of dedicated mobile broadband networks for public safety, and to support the identification of additional spectrum to meet future needs, the TETRA Association has commissioned Analysys Mason to undertake this study to gather information on future public safety user requirements, based on a review of existing documents and reports that have been published in Europe over the past few years and are available in the public domain.

We have reviewed each of the documents (listed in Annex B), with a view to determining:

- the future mobile data and multimedia applications that are envisaged to be in widespread use within the public safety sector over the short and medium term
- the network requirements that are associated with these applications, i.e. the operational requirements of mobile communications networks that will meet public safety user requirements

- the benefits to the public safety sector of the development of a next-generation of dedicated mobile data networks (requiring additional, dedicated spectrum to deliver), compared to the alternative options such as re-engineering of existing or planned commercial networks in Europe.

The authors of this report would like to thank the TETRA Association for their inputs to this study and identification of the relevant documents and reports that have formed the basis of the study's recommendations.

1.1 Summary of applications and user requirements

Current and future public safety mobile data and multimedia applications identified in the various reviewed documents cover a range of needs, including:

- mobile office
- transfer of images
- biometric data
- automatic number plate recognition
- digital mapping and location services
- remote database access
- personnel monitoring
- sensor devices/networks
- remotely controlled devices
- non-real-time video
- real-time video.

Summary of operational requirements essential to public safety mobile communications

The reviewed documents make reference to a number of specific operational requirements that are essential for public safety mobile communications, in order to ensure the availability, reliability and integrity of networks. These include:

- high levels of network availability
- high degree of network control, including the ability to implement prioritised access for specific user groups or individuals, and to reserve capacity where required
- near nationwide geographic coverage, including the ability to communicate in remote areas
- security
- low latency, specifically end-to-end voice delay of no more than 200 milliseconds
- interoperability between different public safety authorities and across borders
- highly resilient networks, including various layers of redundancy
- ability to support mixed traffic.

1.2 Summary of evolution of applications in the public safety sector

There are number of key trends apparent within the daily routines of public safety users, as well as in improved responsiveness at major planned and unplanned events, which are affecting the public safety sector's future mobile data requirements:

- ways of working are changing
- data is being used to enhance voice
- command and control is moving from command centres to the field
- there is greater awareness and use of multimedia.

These trends have been used to develop four alternative evolution paths to illustrate how future use of mobile data and multimedia applications might develop within the public safety sector, as summarised below in Figure 1.1.

Evolution path	*Description*
Steady growth	Working methods change slowly, and voice remains the dominant method of mission critical communication. Existing data applications continue to be used alongside this, with a gradual increase in use.
Data enhances voice	Incident response increasingly relies on situational awareness provided through a range of data applications on the move, and access to a range of faster data applications that can be used in a similar net-centric fashion to that of group-based voice calls (i.e. group sharing and exchange of data).
Information driven	A common operating picture is established at incident scenes through use of mobile command centres alongside central command units, and sharing of information (including voice, text, images, data and video) between the two. This drives requirements for real-time uploading and downloading of information (images, data) between field and control rooms, including use of video conferencing and other on-demand video services to aid communications and incident response.
Full multimedia reliance	A diverse range of mobile broadband applications, including high-quality imaging and real-time video applications take off, with widespread use across the public safety sector. Widespread information sharing improves the establishment of common operating pictures at incidents, facilitates real-time decisions at incidents, and enables the introduction of new video services such as remote medical applications, and personal characteristics recognition.

Figure 1.1: Evolution paths to illustrate alternative views of how future usage might evolve [Source: Analysys Mason]

Our assessment of the implications arising from each of the evolution paths in terms of future network requirements is summarised in Figure 1.2 below.

Evolutionary path	*Outcome*	*Implications*
Steady growth	Minimal changes to existing operational practices, and limited scope to achieve greater efficiencies and responsiveness through new ways of working.	Public safety users will require longer-term retention of existing dedicated networks to meet voice, narrowband and wideband data functionally, however those will be insufficient to meet future mobile broadband needs. This will constrain the development of new working methods and use of a wider range of data and multimedia applications. Limited additional sector-wide benefits are gained through migration to better, faster and more responsive ways of working, but overall growth in data usage is limited by network constraints.
Data enhances voice	Public safety users benefit from significantly greater situational awareness at incident scenes, through sharing and exchange of a range of data and images. Security of data transfer becomes increasingly significant, which limits the usefulness of commercial networks to carry sensitive data traffic.	Existing dedicated narrowband and wideband networks will be insufficient to accommodate the volumes of data traffic that will occur in everyday use. Commercial networks are not deployed to meet the operational requirements for mission-critical data applications, such as secure data transfer, nationwide coverage, guaranteed availability and control. This supports the need for a new generation of dedicated mobile broadband network designed to meet the operational needs of mission critical data.
Information driven	Mobile officers and those in command centres have access to a common picture of incident operations, facilitated by sharing of data, images and other information. This improves decision making, responsiveness and the ability of public safety officers to work in crisis situations, as well as to respond to everyday incidents. Applications such as fingerprint recognition, licence plate recognition, and access to criminal records can all be conducted remotely, in real time.	The need for data applications to be delivered over networks that ensure high availability, resilience and secure communication, and are as reliable as existing TETRA/TETRAPOL voice networks, is increased as a result of the need to access a wider range of applications from anywhere, at any time. Networks must be capable of mobile broadband information upload and download. The need for a more extensive range of mobile applications therefore requires capacity enhancement, similar to the "data enhances voice" path, which will be beyond the capability of existing dedicated networks.
Full multimedia reliance	New ways of working are implemented across the public safety community. A new generation of situational awareness applications are used in daily response as well as for major incidents. Public safety users are able to operate more efficiently, making better use of resources and reducing unnecessary travel. Real-time video is widely used – for example, video calls between mobile command and central command units, real time CCTV image transfer, and remote medicine applications.	With the evolution in data and multimedia applications, and the requirement for those applications to be available over a very wide area (to make applications such as remote telemedicine feasible), existing narrowband and wideband networks will have insufficient capacity and functionality to meet the requirements of this evolutionary path. Similarly, there are limitations in use of commercial networks due to a lack of full geographic coverage, capacity and ability to carry secure data. This evolutionary path therefore requires the development of a new generation of dedicated mobile broadband networks to deliver more network capacity, higher bitrates and a wider range of applications.

Figure 1.2: Impact of different paths on future network requirements [Source: Analysys Mason]

1.3 Summary of options to meet public safety's evolving requirements

It appears that the capabilities of existing narrowband and wideband dedicated mobile networks currently used by the public safety sector will not be sufficient to meet future requirements under three of these four evolution paths. The only evolution path that could be accommodated by existing networks is the "steady growth" path. However, this is not sustainable in the longer term since there is already growing evidence of changes in working methods and trends within the public safety sector that suggest that this path will not match future demands.

A summary of the four alternative evolution paths and their impact on network requirements is provided in Figure 1.3 below.

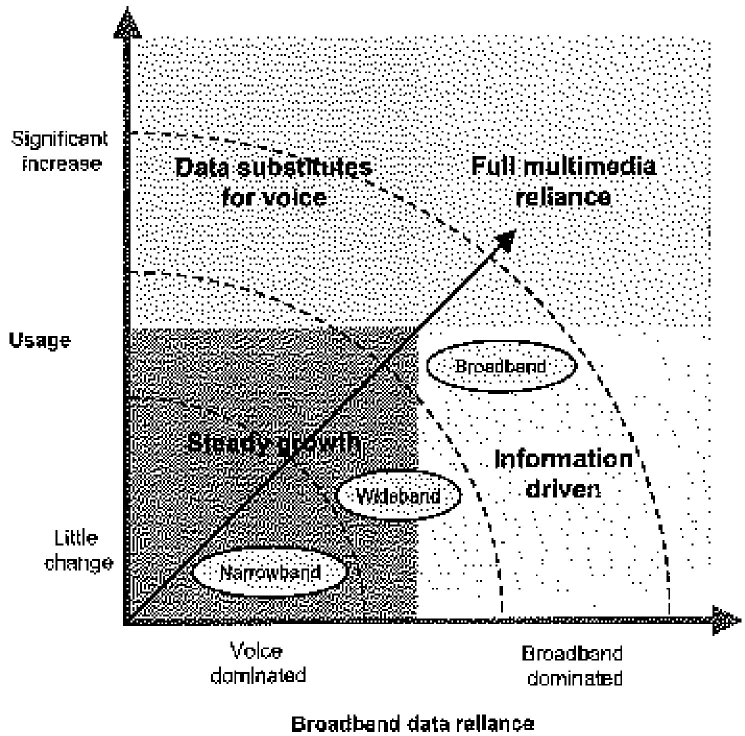

Figure 1.3: The four alternative evolution paths and their impact on network requirements [Source: Analysys Mason]

The four evolutionary paths indicate that a new generation of mobile broadband service is required to accommodate the range of future data, image and multimedia applications that public safety users will demand. The options for delivering this new generation of services are to make use of upgraded commercial networks (e.g. using HSPA+/LTE technology, with network deployment modified to meet the specific operational requirements of the public safety sector), or to develop a new generation of dedicated mobile broadband networks for exclusive public safety use.

While the new generation of data service could theoretically be delivered through upgrading and re-engineering commercial networks, the reviewed documents suggest that this might not be achievable in practice, based on a number of reasons, which range from technical limitations through to cost and commercial considerations.

In particular, there are a number of reasons why commercial operators might be unwilling to make the necessary network changes to support public safety operational needs:

- the public safety sector requires very extensive geographic coverage as well as in-depth coverage penetration inside buildings, irrespective of location, which does not match the typical roll-out requirements of a commercial network
- it is likely to be very expensive to re-engineer commercial networks to achieve all of the public safety sector's operational requirements, and there are questions about whether sufficient incentives exist for commercial operators to do this. For example, typically requirements include the need for battery back-up to be available at thousands of base station sites across the network, and for networks to be designed to ensure that they are highly resilient (including overlapping coverage, standby power supplies and fallback sites) and that no single 'point of failure' exists either in access or core networks
- there are questions about whether some of the public safety requirements are actually achievable
- there is a question about whether the required Grade of Service for public safety use can be guaranteed within a network shared with commercial users, particularly in times of very high traffic loading
- there are conflicting views on whether signalling could be encrypted over the air interface in 3G/LTE
- ensuring the specific requirements for carriage of 'restricted' or 'confidential' documents requires careful network planning and approvals, which is complex and costly to achieve
- it is not clear that networks can be dimensioned to achieve the required immediacy and guaranteed access that public safety requires.

In addition, the reviewed documents presented a further range of reasons why public safety users have been reluctant to make more widespread use of existing commercial networks, and have favoured the development of their own dedicated networks. These include the following.

Coverage	Commercial operators typically invest in coverage where populations exist, and capacity is designed to maximise revenue generation in those areas, with little incentive to invest in areas of low-density population. Public safety, by contrast, requires ubiquitous coverage across a country's geography for everyday use, irrespective of population densities.
Network design	Re-engineering of commercial networks to meet public safety's requirements might be feasible in theory, but in practice would result in large parts of the commercial network being heavily over-engineered. This is likely to be more costly for the public sector to fund than a dedicated network provisioned to meet the specific coverage and capacity needs of the public safety user based, without having to provision for additional commercial traffic.
Sabotage	There is a view that commercial networks might be more vulnerable to sabotage by criminals that dedicated networks are, if the network is known to be used for public safety communications. Dedicated public safety networks are typically more guarded against sabotage through a range of specific measures (e.g. vetted staff, secure fencing at sites, and networks designed to ensure no single point of failure in the event of sabotage, etc.).
Rollout schedules	There are precise requirements for the roll-out of public safety networks (e.g. the need to align with police/fire/ambulance area boundaries), which do not match typical commercial roll-out strategies.
Risks of shared use	There are risks such as information security, quality of service and control of service level agreements if public safety users share networks with commercial users, which previous experience suggests can be avoided through use of dedicated networks under government control and supervision.
Reliance on commercial operators	There is a reluctance for public bodies to be reliant on a fully commercial operator, in view of the potential lack of control upon future network investment, business plans and financing[1].

1.4 Conclusions

The study has found that, in line with societal trends evident within today's Information Society, a diverse range of data, imaging and multimedia applications are in demand within the public safety sector. Demand for access to a wider range of information is being driven by changes in working practices, which is creating requirements for access to a far wider range of data sources (textual, images and video) that is typical in commercial mobile networks. Sharing of various data types (textual, images, video, etc.) is being used in order to establish and maintain a common operational picture between agencies and between field and central command staff. This is being used to improve responsiveness, aid the deployment of resources, and improve timeliness and decision making in daily public safety operations and when responding to major planned or unplanned events.

Three of the four evolutionary paths developed for this study illustrate the public safety sector's need for a next generation of mobile broadband network to deliver the range of applications that are envisaged in the future. As there is a limit to the range and volume of data and multimedia applications that existing dedicated narrowband and wideband networks, and existing commercial

[1] This is referenced, for example, in ETSI TR 102 628 (SRD on additional spectrum requirements for future PSS wireless communication systems in the UHF frequency range, which refers to specific conditions in place in a number of European countries

networks, can provide, if a new generation of mobile broadband network is not made available, some new applications cannot be delivered. Ultimately, this will affect how already emerging changes to ways of working within the public safety might evolve, and, in the longer term, constrain the further development of the sector.

A new generation of services could in theory be delivered using an upgraded commercial network, with the deployment of the network engineered to meet specific public safety requirements. However, as explained in Section 6.2, this option does not appear to be achievable in practice. The only other option is to encourage industry to develop a new generation of mobile broadband networks for dedicated public safety use. To enable the industry to devote the necessary investment to develop new dedicated networks, there is a need for additional spectrum to be identified, since existing bands are already fully utilised by existing dedicated public safety systems. It should be noted that identifying suitable spectrum is on the "critical path" to support development of a new generation of dedicated mission critical mobile broadband solution, because of the timescales associated with identifying suitable spectrum.

This additional spectrum demand is based upon the combination of the various factors identified throughout this report, specifically:

- trends in the range of data and multimedia applications in demand within the public safety sector
- potential increase in user densities and intensity of use for data applications
- specific traffic characteristics of public safety operations (e.g. network-centric ways of working)
- the infrastructure and technical requirements to meet the operational requirements of the public safety community (e.g. availability, security, reliability, latency), and limitations in use of commercial networks to deliver these.

Given the cost of deploying new networks, access to spectrum in bands below 1GHz will ensure maximum commonality with existing dedicated networks deployed in the 380–385/390–395MHz bands, facilitate re-use of assets where possible (e.g. radio sites). Use of spectrum above 1GHz (e.g. bands around 2 GHz) might be feasible but would incur significantly higher roll-out costs compared to that below 1GHz, raising questions at national government level as to whether and how the additional costs can be funded.

Based on the reviewed documents, the European dimension to the public safety spectrum requirement is important for a number of reasons:

- the public safety sector is a niche market and therefore benefits from the identification of harmonised spectrum even more than commercial mobile systems (e.g. GSM or UMTS), because of the smaller user base and resulting lower volumes of equipment and terminals

- even if commercial solutions are adapted to meet specific requirements of a niche sector such as public safety, there are still costs involved in the necessary modifications, and therefore harmonised spectrum availability is key to ensure that manufacturers are able to develop products for a European market. An example of the re-engineering of existing commercial standards to meet niche requirements is that of GSM-R (the railways version of GSM) – although the GSM standard is supported by all major vendors around the world, GSM-R equipment is supplied by relatively few and the availability of harmonised spectrum for the product has therefore been important to reduce costs

- interoperability is an increasingly important requirement within the public safety sector, both to communicate between different public safety authorities within a country, and to communicate across borders. This is evidenced by a number of the documents reviewed for this study.

The lack of available spectrum is therefore a significant barrier to the further development of mobile communications capabilities tailored to meet public safety requirements, until such time as a new, harmonised band can be identified at a European level.

2 Introduction

This report has been prepared by Analysys Mason Limited ('Analysys Mason') on behalf of the TETRA Association, to present the results of a study to review the future needs and requirements for mobile data and multimedia applications within the public safety sector.

For the purposes of this report, the term 'public safety' is assumed to comprise primarily police, fire and ambulance services, although the requirements are also considered to be applicable in a wider Public Protection and Disaster Relief (PPDR) context.

The public safety sector uses a variety of communications networks at present, including a range of fixed voice and data systems within headquarters (HQ), and digital mobile networks while on the move. The majority of public safety users in Europe use dedicated radio networks for their mobile communications that have been designed specifically to meet their needs, typically using TETRA or TETRAPOL digital mobile communications technologies and operating in spectrum in the 380–400 MHz band.[2] This is the frequency band identified at a European level for digital public safety communications as a result of ERC/DEC/(96)01 and subsequent decisions.

While the public safety sector has traditionally relied on voice communication as its primary means of communication at incidents, making particular use of group calls, as well as Direct Mode Operation (DMO) and air to ground voice communications, the requirements for access to a range of mobile data applications have evolved over recent years and are now considered to be an essential part of the public safety sector's mobile communications. This is evidenced, for example, by the dependency on applications such as automatic number plate recognition (ANPR) and access to various databases by police while on the move.

The public safety sector currently has two options to address the use of a wider range of data applications:

- to upgrade existing narrowband networks to provide a wideband overlay (e.g. TEDS), providing wideband data capability
- to continue to make use of existing dedicated networks for mission critical voice and low speed data, and use commercial networks to deliver higher bandwidth, non-mission-critical[3] data.

2 In many countries in Europe, public safety users also make use of existing commercial networks (e.g. GPRS or 3G) in addition to dedicated TETRA/TETRAPOL networks. Commercial networks are often used for the provision of additional vehicle and handheld data services, typically of a non-mission critical nature. This is because commercial networks are not designed to meet the specific functional requirements for mission-critical public safety communications, which requires very high levels of network availability, low latency, very wide area coverage and various levels of security and encryption.

3 'Mission-critical' refers to a service or information for which failure to deliver, disruption or delay is not tolerable in view of its impact on public safety operations.

However, neither of these options is envisaged to meet public safety requirements in the future, since there is a need for a mobile broadband solution that can deliver mission critical high speed data, requiring a network that is designed to meet the specific operational requirements of the public safety sector. Underpinning support for the development of a next-generation of mission critical mobile broadband solution is the identification of suitable spectrum to deploy future systems. This is required because the existing spectrum available for public safety mobile communications is already fully deployed to accommodate today's narrowband and wideband networks.

The TETRA Association has therefore commissioned this study to provide an assessment of future public safety user needs, which will determine future spectrum requirements. Since much of the required information on future public safety needs exists in a range of documents and reports that have been published in Europe over the past few years, the scope of this study has not been to conduct new research into potential future user requirements, but rather to summarise the requirements that are already known to exist through a review of the existing documents.

The remainder of this document is laid out as follows:

- Section 3 describes our overall approach to the study.
- Section 4 reviews the current and future requirements and needs of the public safety sector
- Section 5 considers alternative trends of how public safety needs might evolve
- Section 6 presents the results of our analysis, in terms of options to meet future public safety requirements
- Section 7 presents our conclusions from the study.

The report includes a number of annexes containing supplementary material:

- Annex A provides a list of the acronyms used in this document
- Annex B provides the list of documents that have been reviewed as part of this study
- Annex C includes a summary of our review of each document.

3 Approach to the study

The overall approach to the study is summarised in Figure 3.1 and a brief description of each task is provided below.

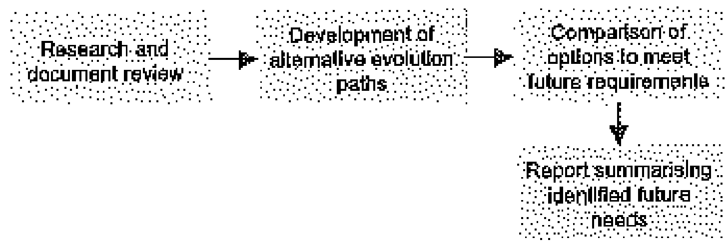

Figure 3.1: *Approach to study [Source: Analysys Mason]*

Research and document review

In this task, a wide selection of documents from a range of public-domain sources (listed in Annex B) were reviewed and used to provide an overall assessment of public safety user needs, and the associated benefits from use of dedicated mobile broadband networks to meet those needs. A summary of the findings from this document review is provided in Annex C.

An objective of this task was to review the forecast demand for data and multimedia applications as presented in the range of existing documents recommended by the TETRA Association for inclusion in this study, including assumptions on requirements for dedicated networks and the benefits of using dedicated networks compared to a shared network.

Development of alternative evolution paths

The first aim of this task was to identify which applications are considered to be driving demand for a new generation of mobile broadband networks for public safety use. This was achieved by summarising the range of applications that were presented in the reviewed documents and grouping them into similar application types.

The second aim of this task was to develop a series of alternative trends for the development of public safety user needs, illustrating how usage might evolve under different alternative views of the future. Four alternative evolution paths were developed, ranging from a steady-growth base case (i.e. continued and slightly increased use of existing applications) to a much greater reliance on a range of traffic types (voice, data and media) within mission-critical environments.

Comparison of options to meet future requirements

In this task, the options available to the public safety sector for providing mobile broadband services were summarised. In addition, the limitations of existing dedicated networks and existing commercial networks to deliver the range of requirements illustrated by the alternative evolution paths were identified, and the public safety user requirements that a new generation of mobile broadband network need to meet were considered.

Report summarising identified future needs

The results of the analysis are contained in the remainder of this report, which forms the main deliverable from the study.

4 Summary of applications and user requirements

4.1 Current and envisaged future mobile applications

Based on an assessment of the currently used applications within the public safety sector, along with those envisaged to be used in the future, it is apparent that public safety mobile communications have traditionally been voice-based, but there is a trend towards using a range of data applications alongside traditional voice applications to enhance communications.

Traditional voice services are widely used for mission-critical mobile communications, and often used in a 'network-centric' fashion[4], evidenced by the widespread use of group calls. Various documents[5] indicate that the requirement for these services will likely continue to exist. The range of voice services that public safety users rely on includes:

- group calls
- encrypted individual and group calls, with authentication
- individual calls to command centre PABX and/or public telephone networks
- direct mode operation between terminals (i.e. terminal-to-terminal communication, without a network)
- emergency calls
- air-to-ground communications.

It is now apparent that a range of data, image and video applications are emerging alongside these traditional voice services, and there is an increasing demand for these data-based applications to be used alongside voice for mission-critical communications, in many cases in a similar 'network-centric' manner to voice.[6]

Examples of emerging applications are described in Figure 4.1 below.

4 'Network-centric' refers to sharing of information between people and devices in a many-to-many (group) configuration, as is often used within the public safety sector.

5 For example, as referred to in results of TETRA Association TEDS workshop, 2007.

6 For example, personalised data is being shared amongst different users at an incident scene, which can offer benefits such as improving the situational awareness of officers at a scene. There is also a trend towards mobile offices, and mobile command and control.

Application	*Description*
Mobile office	Access to mail and intranets, transmission of incident reports from an incident scene or remote location, etc.
Transfer of images	A very wide range of image requirements, including high quality images of damage within buildings, detailed buildings plans, photographs of potential criminals, personal recognition systems (e.g. facial, iris), images of lost children, injuries at incident scenes and other incident-related images required for subsequent evidential purposes.
Biometric data	A greater range of personal recognition systems including fingerprint, facial and iris recognition of potential criminals by officers on patrolling duty, and transfer of this information in real time to HQ/command centres to be checked against biometric records. This improves the efficiency of the potential identification of criminals.
Automatic number plate recognition	A camera captures licence plate details and transmits the image back to HQ/ control centre. This is an application that has emerged in widespread use in a number of countries over the past few years, and its use is expected to continue. Transferring the image back to HQ/command centre enables officers to verify whether the vehicle is stolen, or involved in a crime or other offences. In future, this application could be extended so that image capture and checking against information contained within police databases could be conducted entirely by officers while on patrolling duties, in real time.
Digital mapping and location services	Tracking of vehicles or people, precise geographic positioning (e.g. similar to applications that are provided on commercial mobile handsets to enable navigation and identification of nearest location of interest).
Remote database access	Remote database checks of various types, used increasingly within the public safety sector to retrieve information from databases stored in HQ/command centres by offices on patrol or at incidents. Other databases that could be accessed in real time to support incident response include the Fire Service 'Gazetteer'.
Personnel monitoring	Monitoring of public safety officers in real-time to monitor health conditions while responding to incidents (e.g. fire fighters within a building, or officers involves in search and rescue operations). Other applications might include perimeter monitoring (e.g. of people entering/leaving an incident scene), vehicle or personal alarms, or tracking the location of an assigned individual for general personnel management purposes as well as in the event of an emergency.
Sensor devices/networks	Sensor networks deployed in specific incident areas, used to collect data or images within the area for onward transmission back to HQ/command centres (e.g. collection of thermal imaging from inside buildings reporting on the state of fire or other damage). Fixed or mobile sensors used to record data and images in real time (including images in a video-streaming format), which could then be distributed to other officers at the same incident (e.g. via a sensor network at the incident scene), or back to HQ/command centres. This enables officers in the command centre to have access to the same images as the officers at the incident, enabling real-time decision-making.
Remotely controlled devices	Robotics devices, used to record images within badly damaged buildings that are too unstable for officers to enter, or to operate within explosive areas or in underwater searches. Other applications include remotely turning on or off surveillance microphones or surveillance cameras (including remotely aiming or pointing the camera), and activating and de-activating alarms. Various telemetry systems also in use or envisaged within a range of public safety usage scenarios include control of moving fixed assets (e.g. vehicles, equipment in hospitals, etc.).

Non-real-time video	Capture of video streams at the scene of an incident, which are then stored (e.g. in a vehicle) and downloaded when the vehicle returns to HQ. Could also refer to slow-scan video used to gauge activity at an incident scene, but which is not of sufficient quality to be used as evidence or to support real-time decision-making.
Real-time video	Real-time video surveillance from fixed cameras permanently located along streets and in buildings or from portable cameras mounted on vehicles. Other applications include transmission of video from field officers to command centres, and vice versa, and uses within the health sector, such as remote medical services (e.g. treating patients in rural areas using video calls between the patient's home and the health centre) or treatment of casualties at an incident using real-time transfer of images between responders at the incident area and doctors in hospitals who are able to provide guidance on remote treatment at the incident scene or while the patient is in an ambulance being transported to hospital.

Figure 4.1: Summary of the range of current and future public safety mobile data and multimedia applications [Source: Analysys Mason]

The increase in data, image and video applications is driving, and will continue to drive, demand for greater bandwidth and increased functionality from public safety mobile networks.

A summary of the range of applications that are in current use within the public safety sector, along with their approximate intensity of use (on a scale of high to low use), is provided in the ERO summary of responses to its questionnaire on public safety and disaster relief produced for CEPT FM PT38, as reproduced in Figure 4.2 below.

Intensity of use	*Application*
High	Geo-location identification (of vehicles and people)
	Database query/access
	Short data/messaging
	Direct mode communication
	Image/video/map/plan/photo transfer
Medium	Group calls
	PSTN calls
	Air-to-ground communications
	Command and control (dispatch)
	Data from ambulance to hospital
	Emergency call
Low	WAP queries
	Email and mobile office
	Calls to/from PSTN and office PABX
	Tracking (e.g. RFID)
	Priority call/access
	Trunked operations
	Fire applications
	Video calls
	Radio paging

Figure 4.2: Summary of applications in CEPT WG FM38 survey response [Source: ERO]

A similar range of applications is identified in other documents, such as the ETSI Technical Specification (TS) on requirements for communications between authorities/organizations during emergencies (ETSI TS 102 181). This document also includes a different range of applications, which have been defined in terms of their impact on network throughput, timeliness (i.e. latency) and robustness. This is reproduced in Figure 4.3 below.

Service	*Throughput*	*Timeliness*	*Robustness*
Email	Medium	Low	Low
Imaging	High	Low	Variable
Digital mapping/GIS	High	Variable	Variable
Location services	Low	High	High
Video (real time)	High	High	Low
Video (slow scan)	Medium	Low	Low
Remote database access	Variable	Variable	High
Database replication	High	Low	High
Personnel monitoring	Low	High	High

Figure 4.3: Data services table from ETSI TS 102 181 [Source: ETSI]

Usage scenarios

Various documents[7] include a number of detailed usage scenarios within the public safety sector, which illustrate the range of applications that might be used within daily operations, or to respond to specific incident types. A summary of usage scenarios contained within the reviewed documents is provided in Figure 4.4 below.

7 Operational scenarios are described in a range of documents including references 9 (Mesa), 11 (WIK), 13 (Exler) and 17 (Safecom) – see Annex B.

Figure 4.4: Examples of usage scenarios within public safety [Source: Analysys Mason]

Usage scenario (source)	*Summary of applications used*
Patient services for a car crash (US Department of Homeland Security)	• Video conference call set up between the ambulance and the hospital • Ambulance's geo-location, along with vital measurements and treatments of the patient, recorded from the ambulance and transmitted wirelessly to the hospital
Major explosion/bomb (MESA/TS 70.001 v3.3.1)	• GIS used by police to establish the perimeters for the incident scene • Initial casualties information forwarded to hospitals, including images of injuries taken at the incident scene • Real-time video feeds relayed to the control room of the incident area • Fire fighters enter damaged buildings using bio-telemetry devices to monitor people and conditions within the building • Robotic devices used to confirm that no other explosives are present • Crime scene diagrams constructed using portable laptops at scene of incident • Images recorded as evidence by investigators at the scene
Traffic stop (US Department of Homeland Security)	• Situation message, police vehicle's ID and geo-location transmitted from police car at the scene of incident to other offices and to command centre • Suspect's licence plate read and sent to command centre, and queried against several databases located at HQ • Results from database query send back to police car • Video stream of the action at the incident transmitted and stored in central database, and made available on demand to dispatch/command centre. Onward message sent to other offices, along with video footage, to arrest the suspect • Arresting officer's ID loaded onto RFID handcuffs • Suspect's biometric data taken at incident scene, stored and forwarded to command centre • Case report sent electronically from arresting officer's car
Large earthquake in urban area, with many damaged buildings (MESA)	• Virtual treatment centre set up at incident scene; buildings surveyed for damage and identification of locations of further casualties • Handheld computers used to sketch building structures, entrances, etc. • Mobile command centre set up • Hazardous zones identified in buildings; fire fighters equipped with personal monitors and location tracking devices to enter hazardous areas

Large international finance summit (scenario developed by a UK agency)	• Mobile command centre established at venue, for in-building communications and to establish perimeter control, linking to central command units of police, fire and ambulance authorities • Establishment of a common operating picture using a range of data types (images, text, voice, video) • A range of mobile broadband at-venue applications available including o Enhanced personal recognition systems (iris, facial) o Ability for ambulance service to send high-quality video streams from the venue and from vehicles to hospitals, if required o Ability for fire service to send high-quality video streams from venue to command centre (e.g. in-building plans, structural plans, etc.) o CCTV camera images captured from the venue and distributed to central command centres in real time o Ability to track people and objects within the venue
Large fire in a high rise building (TR 102 485 : Technical characteristics for Broadband Disaster Relief applications (BB-DR) for emergency services in disaster situations)	• A scenario involving fire and rescue and police rapid response – within a concentrated area of $1km^2$ • Personnel protection and surveillance using sensors with panic alarms • Thermal image video capture and transmission • Asset tracking within the incident area • Video surveillance across the incident area • Perimeter zone control to track all cars going in and out of a fixed location • Data capture and control devices to capture or deliver data to the point of decision within the incident area • Back office applications enabling a range of business functions within the area

All of the above examples suggest that future public safety operations will rely on the availability of multiple data, imaging and video applications as well as voice, and demonstrate the necessity for applications to be supported within a single network, to ensure interoperability between different public safety authorities/organisations involved in the response of a specific incident.

4.2 Operational requirements essential to public safety mobile communications

Public safety networks have features that are distinct from those of commercial networks, as they need to be able to support mission-critical applications that have unique technical and operational requirements such as extensive coverage, capacity, reliability, immediacy of communications, security, redundancy and resilience. Other requirements also include the ability to support non-voice applications (in real time and non real time), interoperability within the organisation, as well as other emergency services, and cross-border communications.

The documents and reports that were reviewed make reference to a number of these operational requirements, as summarised in Figure 4.5 below.

Requirement	*Summary*
Availability	Availability in time is specified as three or four 'nines of availability' (e.g. 99.98% or better at all times) for some users. Others specify different requirements for different times, such as 99.9% per year, 99.7% per month and 99% per 24 hours (e.g. as referenced in CEPT FM38 questionnaire response on PPDR from the Denmark administration). This high degree of availability includes access to networks in all areas at all times (including under very high traffic loading conditions during which it may be necessary to reserve capacity for specific incident responders).
Control	A high degree of network control is required (e.g. to enable prioritised access or reserved capacity to be guaranteed when required)[8]. Control requirements also include the ability to queue traffic, and to manage queuing conditions and update these in real time.
Coverage	Public safety network coverage requirements differ from those of commercial networks, which are typically designed to cover areas where populations live (and therefore may provide near-100% population coverage, but do not provide the same level of geographic coverage). The public safety sector, by contrast, requires much wider geographic coverage, and the availability of the same set of applications across all geographies. Coverage must also be consistent with typical organisational boundaries within the various public safety services. Coverage requirements are specified as, for example, 99.5% (outdoor mobile), 65% or better (indoor mobile), 99.9% (air to ground).[7] Another document from a UK agency refers to at least 99% of the landmass of Great Britain needing to be covered (including offshore islands).[7]
Security	Security requirements are guided by national security and accreditation requirements, which vary in different countries. TETRA provides different layers of encryption including over-the-air and end-to-end (better than 80-bit encryption is referred to in documents we have reviewed). Other security features include two-way authentication.
Low latency	There are requirements for very short call set-up times and for limited end-to-end voice / data transmission delay (for mission-critical applications). One document refers to end-to-end voice delay being no more than 200 milliseconds.[9]

8 E.g. referenced in various replies to the ERO questionnaire on PPDR on behalf of CEPT WGFM PT38 and in ETSI TR 102 628

9 For example, as referred to in various replies to ERO questionnaire on PPDR of CEPT WGFM PT38.

Interoperability	There is an established need for different units within the public safety sector to interoperate (e.g. police, fire and ambulance, and associated services), requiring each to use the same technology. In addition, there is a growing awareness of the benefits of cross-border interoperability between different public safety units operating in different European countries.
Resilience	Networks must be highly resilient and include various layers of redundancy. Central network switching must be fully redundant, with geographically distributed switching. Interconnection between base stations must also be fully resilient and include back-up lines between key base stations. Back-up power supplies are required at different levels – for some key sites, there is requirement for up to seven-day back-up in some instances. Key base stations sites (i.e. a selected number of sites from within the overall network) need to have fallback sites available in the event of failure of the primary site.
Ability to support mixed traffic (i.e. voice and data)	An integrated network solution providing support for transmission of mixed traffic types (e.g. voice, data, images) is a requirement for public safety, in order to be able to use the same technology in all environments (e.g. ranging from day-to-day emergency response to major planned incidents and major disasters/unplanned incidents).

Figure 4.5: Public safety mobile communications operational requirements [Source: Analysys Mason]

These essential operational requirements are unlikely to change in the future, and moving forward a more diverse range network-centric requirements might be envisaged, based on increasing use of sensors and sharing of information, images and video. In particular, the occurrence of various major incidents around the world has reinforced the need for core operational requirements to be maintained in current and future-generation of public safety networks.

While future commercial networks (e.g. LTE) may be able to offer the required range of data services that are envisaged to support the usage scenarios described in Section 4.1, there will still be challenges to ensure that the operational requirements of the public safety sector can be met, particularly as commercial networks are typically optimised for financial return on investment rather than to deliver services across a wide geography (irrespective of population centres), which is what the public safety sector requires.

At present, commercial networks are not deployed to meet the core operational requirements for public safety use for a number of other reasons:

- commercial coverage, even for GPRS, is typically not nationwide and is often limited inside buildings
- 3G and LTE are likely to be deployed in 'islands' of coverage, rather than nationwide
- roll-out of sites will not be at a pace or geographically suited for a public safety network
- queued calls and the ability to control/configure queuing conditions is not provided
- there are no provisions in current standards for pre-emption capabilities or preferential measures which would guarantee capacity for public safety users in times of heavy traffic
- there are no provisions for two-way authentication or integral Direct Mode (i.e. terminal-to-terminal capability)
- there are potential issues with transporting secure information over a shared public network, both in relation to over-the-air conveyance and end-to-end encryption

- redundant switching is required for public safety applications, which commercial networks do not always guarantee
- no single point of failure must exist within the network
- high availability is not guaranteed (e.g. three or four nines of availability at all times is a typical requirement for public safety applications).[10]

10 Availability in time is also specified as 99.9% per year, 99.7% per month and 99% per 24 hours in the Danish response to the ERO questionnaire on PPDR.

5 Evolution of applications in the public safety sector

5.1 Trends in the use of mobile applications in the public safety sector

The public safety sector is following the same trends that are apparent within the wider society for access to a wide range of information on the move, and sharing of knowledge and information.

This, and a number of other trends evident within the public safety sector, is driving demand for mobile data requirements, as summarised in Figure 5.1 below.

Changes to ways of working	Ways of working are changing within the public safety sector – for example, there is a trend towards mobile command and control to enhance the effectiveness and efficiency of incident response. This is driving demand for simultaneous access to a much wider range of applications, which are being used in combination to respond to an individual incident.
Data enhancing voice	Public safety users are increasingly using data applications to enhance the mission-critical voice communications that they rely on for daily use and when managing planned and unplanned major events.
Information-driven operations	Usage scenarios for how public safety users work on a day-to-day basis while out on patrol or away from command centres suggest that usage is evolving towards greater sharing of information from a variety of sources (voice, data and video). The overall purpose and objective of this way of working is to establish common operating picture between all public safety agencies and between officers at incidents and those in HQ command centres, thus improving situational awareness. This has many benefits including better mobilisation of field teams, more timely response and more accurate information available to support decisions on incident response.
Greater awareness and use of multimedia	Increasingly more daily routines are taking advantage of a mixture of different traffic types (i.e. voice, data, images, video), which is supported by the trends towards mobile field operations and mobile offices. This requires access to the same range of applications while in the field as an officer would have while in a command centre. Multimedia applications extend across different network types, from wide-area transmission across field boundaries, through to local area transfer of incident-specific information, to personal area networking and the collection and transfer of data collected by remote sensors and/or tracking devices.

Figure 5.1: Trends affecting public safety sector requirements [Source: Analysys Mason]

The reviewed documents indicate that the range of applications in demand within the public safety sector is extending significantly beyond the 'traditional' core, group-call-based voice and data applications that have been previously associated with the sector. Interactive multimedia services, access to office applications while on the move, and a range of sensing, robotic and telemetry applications are all in demand. In addition, over time it is expected that both the range and the intensity of use of different applications will increase. This requires much higher data speeds and additional dedicated network capacity to be available, with applications being accessible through handheld devices used indoors or outdoors, and to vehicle-based users.

5.2 Alternative evolutionary paths

To explore how demand for different applications might evolve over time, and the impact of this evolution on network requirements (i.e. availability, speed and capacity), a series of alternative evolutionary paths for the public safety market have been developed. These have been built based upon the consensus regarding the range of applications that might be used within the public safety sector in the future, as ascertained from the reviewed documents. This is illustrated in Figure 5.2 below, with the applications shown in comparison to their impact on network capacity requirements (i.e. low to high capacity requirement) and their estimated stage of development (i.e. available now or envisaged in next 3–5 years).

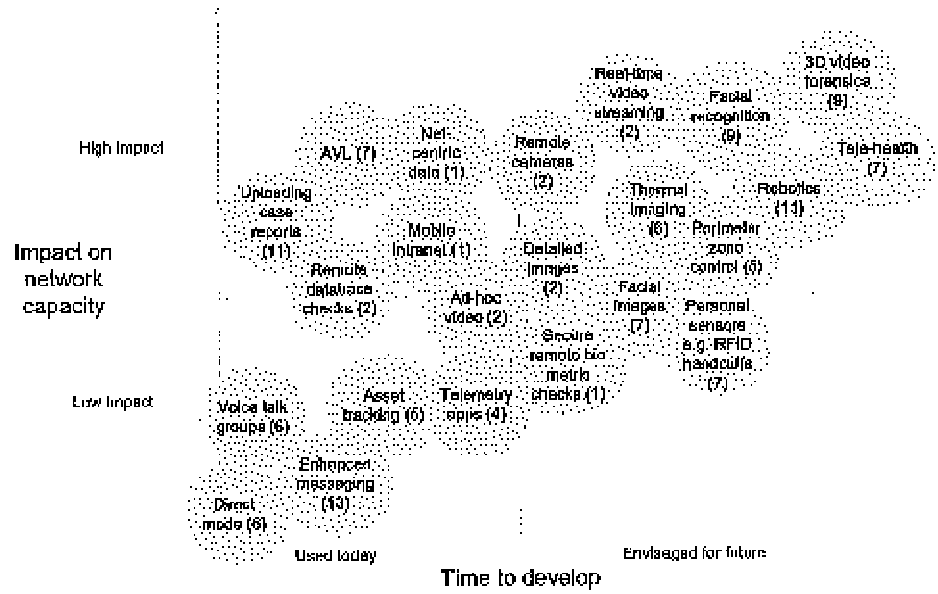

Figure 5.2: Illustration of how demand for multimedia applications might evolve within the public safety sector, and impact on network capacity [Source: Analysys Mason, various documents[11]]

Specifically, based on the envisaged range of applications in demand within the public safety sector, and an estimation of the time necessary for them to develop into full operational use, we

[11] Numbers in brackets refer to documents listed in Annex B which make reference to the various applications illustrated in this diagram.

have developed four alternative views of how data and multimedia applications usage might evolve.

These four evolutionary paths are summarised in Figure 5.3 and described in more detail below.

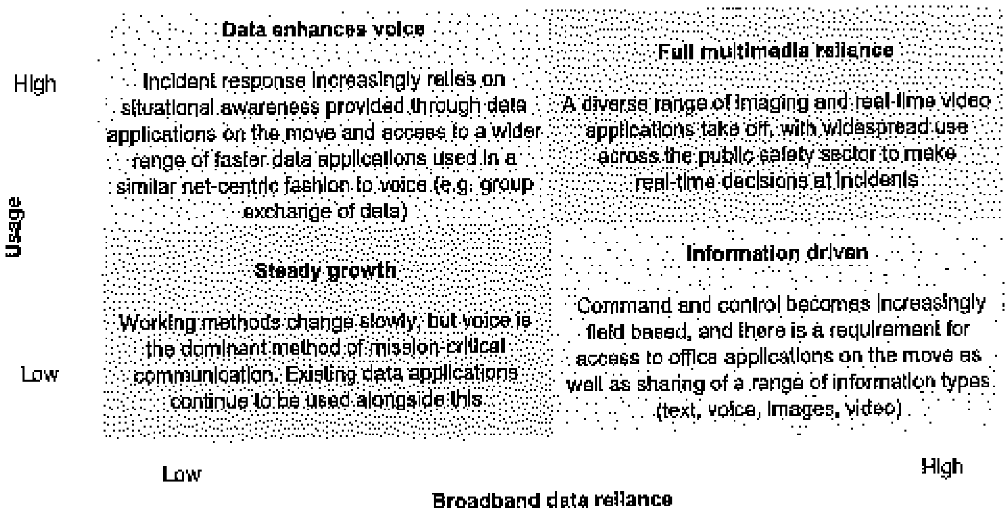

Figure 5.3: Four alternative evolution paths for use of data and multimedia applications within the public safety sector [Source: Analysys Mason]

5.2.1 Steady growth

The "steady growth" path represents the base case for market evolution within the public safety sector, under the assumption that there are no major changes to requirements or significant deviations from currently observed usage trends.

In this evolutionary path, there is a continuation of current usage patterns already evident within the sector, with a wider range of data applications being used alongside group-based voice calls. This combination of traffic types (i.e. voice and data) is evident both in daily operations and in responses to major incidents, however, mission-critical communications continue to use voice as the main delivery method, using established networks. Data usage continues to grow, but at a slow pace, constrained by lack of availability of dedicated, secure, data capacity that meets the public safety sector's core operational requirements. The communications strategy is therefore to continue to use the existing generation of dedicated TETRA network, upgraded to TEDS where practical, alongside commercial networks that are used to carry non-mission-critical data. However, it is unlikely that this strategy can be sustained indefinitely, given that the intensity of data usage will inevitably increase in line with current trends (evidenced, for example, by the significant increase in use of ANPR in recent years).

A summary of the implications of this evolutionary path is provided below.

Trend	Continuation of existing trends with greater volumes of data use, but constrained by lack of suitable networks to deliver mission-critical data in high volumes.
Outcome	Minimal changes to existing operational practices, and limited scope to achieve greater efficiencies and responsiveness through new ways of working.
Implications	Public safety users will require longer-term retention of TETRA and TEDS networks to meet voice, narrowband and wideband data functionally. This will constrain the development of new working methods and use of a wider range of data and multimedia applications. Limited additional sector-wide benefits are gained through migration to better, faster and more responsive ways of working, but overall growth in data usage is limited by network constraints.

Figure 5.4: Summary of "steady growth" evolutionary path [Source: Analysys Mason]

5.2.2 Data enhances voice

A key driver of the market for public safety applications is the trend towards network-centricity in data and multimedia operations. Similar to when using group-based voice calls, public safety users have a requirement to share data and multimedia applications on a many-to-many basis in order to ensure that everyone involved in a specific incident response is fully briefed on all information and decision making is undertaken accordingly. This manifests in the increasing demand for use of data to improve situational awareness, gained from a mixture of telemetry, sensor and video applications.

The "data enhances voice" path represents this trend of demand for access to data in combination with voice, used in a network-centric way. This path can therefore be summarised as being an extension of the current trends for greater access to data applications being used alongside voice, but with data applications becoming increasingly essential to mission-critical responsiveness. Over time, it is expected that a gradual reduction in group-based voice calls will occur as more and more communication takes place via transfer of data and images.

A summary of the implications of this evolutionary path is provided below.

Trend	Data is used alongside voice to enhance flow of information occurring in daily public safety activities and for incident response. Widespread adoption of data applications means that the capacity available on existing dedicated TETRA/TEDS networks is not sufficient to carry the data traffic that will be generated.
Outcome	Public safety users benefit from significantly greater situational awareness at incident scenes, through sharing and exchange of a range of data and images. Security of data transfer becomes increasingly significant, which limits the usefulness of commercial networks to carry sensitive data traffic.
Implications	Existing dedicated narrowband and wideband networks are not sufficient to accommodate the volumes of data traffic that will occur in everyday use. Commercial networks are not able to deliver the required functionality to accommodate secure data transfer, or the capacity or coverage to achieve the necessary network-centric ways of working. This supports the need for a new generation of dedicated mobile broadband networks.

Figure 5.5: Summary of "data enhances voice" evolutionary path [Source: Analysys Mason]

5.2.3 Information driven

There is consensus amongst various reviewed documents that there is trend towards mobile command and control in other words, enhancing traditional HQ-based command centres with mobile command centres that are set up to respond to specific events on a daily basis, or set up to assist the smooth operation of major planned events (e.g. New Years Eve celebrations, major sporting events, etc.). This drives demand to establish a common operating picture between the venue/incident and central control rooms, achieved through sharing of various information (voice, images, video). In addition, knowledge-based working requires public safety officers to have access to the full range of applications available to them in the office, whilst in vehicles or on the move.

These applications could be accessed using hand-held devices or through vehicle-based devices. Users will require immediate access to information stored in databases in order to manage command and control from the incident scene. The direction of data is both uplink (in order to transmit various images, data and video from the scene of incidents to central command) and downlink (e.g. from command centre to the incident scene, to assign resources or respond to information requests). There will also be a greater demand for mobile office applications to complete incident reports remotely rather than upon returning to HQ/command centres. As with the "data enhances voice" evolution path, there will be a greater demand for access to a wider range of data and imaging applications to enhance situational awareness and responsiveness. This will include sensory devices to gather information on conditions of buildings and people, and the ability to exchange this information wirelessly between different incident responders. Greater volumes of mission-critical data traffic will therefore emerge, which cannot be delivered by commercial networks operating on a 'best efforts' basis.[12]

12 'Best efforts' in this context refers to data that can tolerate delay or interruption, i.e. is non-mission critical.

As with the "data enhances voice" evolution path, the "information driven" path will generate data volumes that will exceed the capabilities of existing dedicated narrowband and wideband networks, and require a new generation of dedicated mobile broadband networks.

A summary of the implications of this evolutionary path is provided below.

Trend	There is a demand for access to the same range of applications in the field as those available at HQ/command and control. This includes widespread use of mobile office applications, as well as remote access to databases and ability to view, replicate and update information in real time.
Outcome	Mobile officers and those in command centres have access to a common range of situational pictures, data and other information. This improves responsiveness and the ability for public safety officers to work in crisis situations, as well as to respond to everyday incidents. Applications such as fingerprint recognition, licence plate recognition, and access to criminal records can all be conducted remotely, in real time.
Implications	The need for data applications to be delivered over networks that ensure high availability, resilience and secure communication, and are as reliable as existing TETRA voice networks, is increased as a result of the demand to access a wider range of applications from anywhere, at any time. The need for a more extensive range of mobile applications therefore requires capacity enhancement, similar to the "data enhances voice" path, which is beyond the capability of existing TETRA and TEDS networks.

Figure 5.6: Summary of "information driven" evolutionary path [Source: Analysys Mason]

5.2.4 Full multimedia reliance

In the "full multimedia reliance" path, there is a dramatic increase in both the range and intensity of use of new and innovative data and multimedia applications, including video streaming which is necessary for real-time interactive services such as telemedicine, 3D video forensics and high-quality evidential facial recognition applications. Public safety users start to make significant use of video applications alongside voice and data, driving demand for a wide range of applications to be made available over a common network interface to aid interoperability. Similar to the "data enhances voice" scenario, there is a widespread take-up of a range of data applications used in a network-centric manner. Alongside this, however, video streaming is used to further improve situational awareness at incidents and to enable a common operating picture to be established (e.g. through use of video conference calls, live CCTV video footage streaming, etc.). Future applications such as telemedicine are rolled out to improve access to medical services in rural areas. This requires access to a mobile broadband network covering a wide geographic area in order to reach the remotest areas, since the public safety organisations cannot control where unplanned incidents occur. New ways of working fully evolve so that there is substantially less reliance on HQ/command centres to store, retrieve and deliver information, since users are able to access a full range of applications while on the move.

As with the "data enhances voice" and the "information driven" paths, this evolutionary path will generate data volumes that will exceed the capabilities of existing dedicated narrowband and wideband networks, and require a new generation of dedicated mobile broadband networks.

A summary of the implications of this evolutionary path is provided below.

Trend	There is full reliance upon a wide range of traffic types (voice, data, video) in order to respond to new ways of working, and roll-out of new services such as remote telemedicine and 3D forensics. There is widespread take-up of a wide range of mobile data applications similar to the other evolution paths, alongside new multimedia applications.
Outcome	New ways of working are implemented across the public safety community and users are no longer constrained by having to return to HQ/command centres to complete certain tasks. A new generation of situational awareness applications are used in daily response as well as for major incidents. Public safety users are able to operate more efficiently, making better use of resources and reducing unnecessary travel.
Implications	With the evolution in data and multimedia applications, and the requirement for those applications to be available over a very wide area (to make applications such as remote telemedicine feasible), existing narrowband and wideband networks have insufficient capacity and functionality to meet the requirements of this evolutionary path. Similarly, there are limitations in use of commercial networks due to a lack of full geographic coverage, capacity and ability to carry secure data. This evolutionary path therefore requires the development of a new generation of dedicated mobile broadband networks to deliver more network capacity, higher bitrates and a wider range of applications.

Figure 5.7: Summary of full multimedia reliance evolutionary path [Source: Analysys Mason]

5.3 Mapping of applications to the four alternative evolutionary paths

The range of applications detailed in the various documents reviewed for this study have been mapped to the four alternative evolution paths as described above, in order to provide examples of how the use and range of applications might develop across the different evolution paths.

This mapping is summarised in Figure 5.8 below. Note that the numbers in brackets indicate references to the documents listed in Annex B. It should also be noted that since voice requirements are assumed to remain constant across all of the four evolutionary paths, voice is not included in the mapping table, although it is assumed to remain as an essential requirement for public safety operations.

Figure 5.8: *Mapping of data applications to trends [Source: Analysys Mason]*

Application	*Steady growth*	*Data enhances voice*	*Information driven*	*Full multimedia reliance*
Mobile office	Status messages, either field to field or command to field, are delivered by email in addition to short data/short messages, for resource allocation and incident control [2, 3, 6]	Emails/office applications are used for administrative messages, and access to emails and intranet whilst out of the office improves timely response to requests [1, 2, 17]	Increasing access to web applications (e.g. Intranet and Internet, online access to contacts databases etc.) is made, enabling incident reporting to be handled via mobile devices, reducing the need to return to HQ/command centre to access office applications [2, 5, 6, 17]	Incident-specific information exchanged using web applications (e.g. language translation, web-addressable cameras) in addition to use of a wide range of Mobile Office applications (contacts databases, email, Intranet) [5, 17, 18]
Database queries/updates	Database checks conducted in vehicles and via hand-held devices (e.g. passport information, Gazetteer, criminal records, patient records) [1, 2, 6]	Increased ability to updated databases with textual inputs in real time to provide additional incident details, or patient record updates whilst on the move [1, 2, 17]	Additional data updates provided from incidents and uploaded in real time (e.g. visual information, results of biometric checks) [6, 17]	Increasing upload/download of data and updating in real time (e.g. ECG traces) plus development/update of architectural plans of buildings from incident scenes [7, 8, 11]
Location-based applications	Use of geographical positioning tools (e.g. GIS) [2, 5, 6]	Asset tracking (e.g. of people and equipment) with positional information sent periodically to HQ/command centre [2, 6, 7]	Increasing use of self-forming networks (e.g. perimeter tracking at incident scenes and machine-to-machine communications) [1] [2] [6]	Fully integrated tracking / surveillance / image systems used in real time (e.g. to record location and status of fire fighters and people within a building), along with video robotics (e.g. to capture information in explosive environments) [8]
Digital mapping	Used for navigation and access to digital maps [2]	Access to 3D geographic images [1, 2]	Increasing use of images of different types and quality e.g. aerial views of incidents, high quality imagery [1, 2, 5]	Live 3D views inside buildings, and mapping of personnel and casualty locations [9]

Biometric monitoring	Use of basic telemetry applications [2, 5]	RFID used for tracking of personnel at incidents [2, 5, 7]	Biometric monitoring of personnel conditions over time [5, 7, 11]	Body worn sensors (e.g. object impact on helmet or vest, RFID-handcuffs) providing real time monitoring and information updates, improving real time structural awareness [7, 17]
Still images	Image and audio capture at incidents (e.g. push images of suspects and missing persons to field officers and images of fingerprints stored in central databases) [1, 2, 6]	Gathering of evidence at crime and incident scenes, and collation of witness information using field devices (e.g. incident scene photo transfers) [1, 2, 7]	Transmission of building floor plans and use of thermal image capture and transmission [1, 2, 7]	Evidential-quality image capture, and/or very detailed images (e.g. burns or other injuries [1, 7, 11]
Slow scan video	Sequence of fixed images exchanged between command centre and officers in the field [2, 6, 11]	Limited motion video captured and available on demand to command rooms and dispatch [5, 6, 7]	Video conference calls between field and command centre to support incident response and decision making [6, 9, 11]	Information captured by surveillance cameras at incident scenes relayed to command centres in real time, forming an essential element of mission critical communications and decision making [17, 18]
Real-time video	Relaying of ad-hoc video and surveillance camera information to control cars responding to incidents, and real-time traffic flow monitoring [7, 11, 19]	Upload of real-time standard definition video (e.g. from cars or handheld devices to command centre) [5, 7, 11, 19]	Live high definition, mission critical video footage transferred between incident and command (e.g. from ambulance to hospital), and use of mobile video conferencing [2, 6, 8]	3D video forensic applications, telemedicine and sophisticated airborne video platforms communicating with mobile devices [3, 8, 17]

6 Options to meet public safety's evolving requirements

6.1 Options to provide mobile broadband services to the public safety sector

As demonstrated in the previous sections, the various documents reviewed for this study indicate a general consensus that a wide range of data and multimedia applications will be required to meet future user demands within the public safety sector. The four alternative evolutionary paths developed for this study illustrate how demand for those applications might evolve over time, in line with changes to ways of working that are already evident with the public safety sector, such as a greater demand for mobile working, and increasing sharing of information to establish a common operating picture, often requiring upload of significant volumes of data of different types (e.g. images, video).

The options available to the public safety sector to deliver the envisaged range of applications under the different evolution paths are as follows:

- continue to use the existing generation of dedicated networks, and upgrade those to deliver wide band functionality (e.g. using TEDS).
- continue to use existing narrowband and wideband networks, and use existing commercial networks to provide additional, non-mission critical, data services
- develop a new generation of mission-critical mobile broadband network solution, either by developing a new generation of dedicated mobile broadband network or by upgrading existing commercial networks (e.g. based on HSPA+/LTE) and engineering their deployment to deliver the required public safety operational requirements of availability, coverage, security and control.

From our analysis, it is clear that, with the exception of the "steady growth" path, each of the other evolution paths will require additional high-bitrate data and multimedia applications beyond the capabilities of existing dedicated narrowband and wideband networks. Similarly, current commercial networks will not be able to support the range of envisaged applications, and in any case will not, as current deployed, meet the operational requirements of the public safety sector in terms of wide area coverage, security, resilience, control and availability.

There is growing evidence of the need for public safety to access multiple data applications simultaneously in order to establish a common operating picture, which requires use of a common infrastructure to avoid the need for multiple handsets and solutions. This is particularly true in the case of responding to major incidents, which require much more intensive use of a wider range of applications but using the same equipment and networks that are used in daily public safety operations. The combination of existing dedicated networks and existing commercial networks does not meet these requirements.

The advancement of network functionality requirements in line with the alternative evolution paths developed for this study is summarised below.

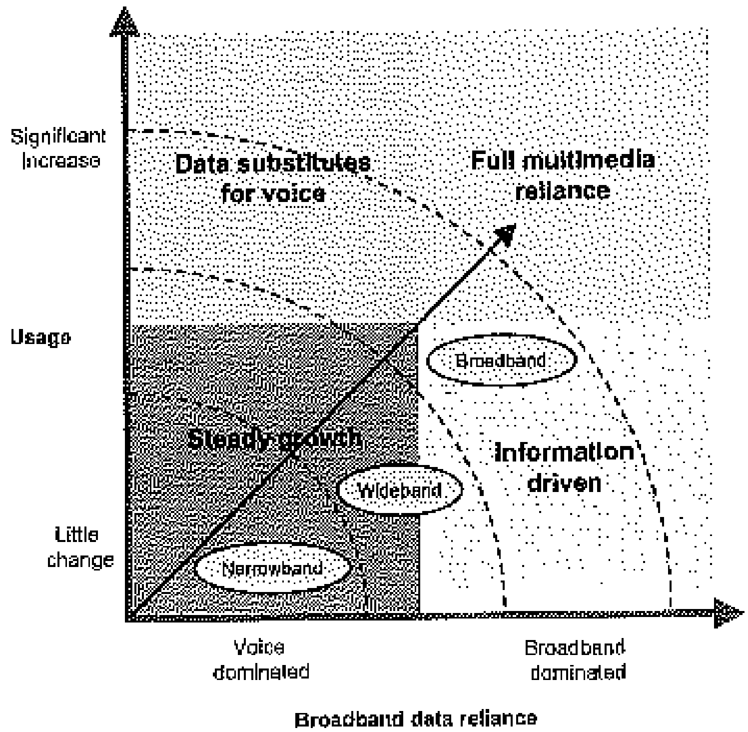

Figure 6.1: The four alternative evolution paths and their impact on network requirements [Source: Analysys Mason]

As described in Section 5.2, it appears that the "steady growth" path cannot be sustained indefinitely, given that the intensity of data usage is already increasing in line with current trends (evidenced, for example, by the significant increase in use of ANPR in recent years). This suggests that the only feasible option to meet the future evolution of public safety user requirements is to develop a new generation of mobile broadband network.

This conclusion is further evidenced by the range of usage scenarios that various documents envisaged within the public safety sector, as described in Section 4.1. The range of applications in concurrent use within these different usage scenarios demonstrates that, without a new generation of mobile broadband service being available, the full range of applications within the various scenarios will not be available in practice. This is summarised in Figure 6.2 below.

Figure 6.2: *Benefits of the development of a new generation of mobile broadband services for public safety use [Source: Analysys Mason]*

Usage scenario	*Existing public safety networks*	*Existing public safety networks plus commercial networks*	*Upgraded commercial network or new dedicated mobile broadband networks*
Patient service at car crash	Limited bandwidth to deliver video calls and images of patient injuries from ambulance to hospital, resulting in less timely response	Transferring sensitive patient records between ambulance and hospital not possible over commercial networks due to security and bandwidth limitations, leading to less timely response, and more manual paperwork	Faster identification of crash location, transfer of patient details in real time means improved emergency service response and enables more rapid diagnosis and treatment
Major explosion	Many of the envisaged applications not supported by current networks due to lack of bandwidth and limited data rate (e.g. incident perimeter tracking, real-time video feeds and bio-telemetry), resulting in less timely response, need for more resources and manual recording of information	'Best effort' nature of commercial networks means that they cannot be relied on in major incident situations. Public safety users are limited to using applications available on their dedicated networks, resulting in reduced interoperability, need for more resources, additional manual paperwork and reduced ability for crisis management	Interdepartmental communications maintained through secure, interoperable network, and network dimensioning to enable network-centric voice and data transfer improves efficiency of operational response to major incidents and more effective resource deployment, awareness and management
Traffic stop	Limited ability to capture and transmit information from the scene. ANPR in use today but increasing volumes of use mean that there are capacity constraints	Secure transfer of personal information not possible over a public network, reducing ability to capture and transfer information from the scene and possibly reducing ability to apprehend the criminal	Real-time identification of suspects and criminals, more timely response and better crime response rate
Earthquake	Mobile command and virtual treatment centre not possible using current generation of networks, leading to less effective, slower response, duplication of information and reduced ability to make real-time decisions	Levels of commercial traffic in this urban area would be high and so it is unlikely sufficient capacity can be dimensioned for public safety use. Loss of benefits such as slower response and duplication of information	Virtual treatment centre made possible through availability of higher speed, dedicated capacity leading to real-time diagnosis and treatment, better use of resources, and reduction in ambulance-hospital journeys
Fire at depot	This operational scenario illustrates that the only reliable mission critical communication methods at present are voice and low-speed data, limiting responsiveness and flow of information	'Best effort' nature of commercial networks means that reliable video transfer is not possible, reducing ability to decide upon evacuation in real time, and higher risk to deployed resources	Capture and transfer of building information and images in real time deliver more efficient decision making, better resource deployment and safer working environment for fire fighters
Large international finance summit	Relies on common operating picture being established between mobile command centre at the venue and central control rooms – this requires exchange of a range of information (voice, images, video) that are beyond the capabilities of existing dedicated networks	Transfer of sensitive personal data (e.g. iris or facial recognition) is not possible using a non-secure commercial networks. Requirement for high quality imaging applications to be available inside the venue also limits usefulness of commercial networks that do not always provide the necessary depth of indoor coverage	Capture and transfer of video and images in real time delivers a common operating picture, enabling more efficient decision making, better resource deployment and safer working environment for the summit

6.2 Limitations of upgrading commercial networks for future public safety services

As indicated in the section above, new mobile broadband services to meet future public safety user requirements could, in theory, be provided by upgrading commercial networks and engineering the deployment of these to achieve the specific operational requirements of the public safety sector. However, the consensus of the various reviewed documents is that there are a number of critical limitations inherent in using commercial networks for public safety applications, due to the core operational requirements that public safety communications need to meet.

While in theory it might be possible to upgrade and engineer commercial networks to meet these operational requirements (i.e. build new, shared, LTE networks that are engineered to meet both public safety and commercial user requirements), the balance of evidence in the reviewed documents suggests that this will be unachievable in practice. In particular, there are a number of reasons why commercial operators might be unwilling to make the necessary network changes to support public safety operational needs:

- the public safety sector requires very extensive geographic coverage as well as in-depth coverage penetration inside buildings, irrespective of location, which does not match the typical roll-out requirements of a commercial network
- it is likely to be very expensive to re-engineer commercial networks to achieve all of the public safety sector's operational requirements, and there are questions about whether sufficient incentives exist for commercial operators to do this. For example, typically requirements include the need for battery back-up to be available at thousands of base station sites across the network, and for networks to be designed to ensure that no single 'point of failure' exists either in access or core networks
- even if re-engineering costs are borne by the public sector, there is a risk that the resulting network will then be over-provisioned for commercial use. As such, commercial operators might find themselves having to pass additional costs (e.g. for the ongoing operation and maintenance of the network) on to commercial user tariffs, which is not viable given the competitive nature of the commercial mobile market. As such, commercial operators may not be willing to take on such requirements, given the potential risk to their commercial business
- there are questions about whether some of the public safety requirements are actually achievable. For example, to obtain the necessary layers of redundancy and prioritised access to capacity in urban areas might not be possible (since demand for capacity will also be high from commercial users, and hence reserving capacity specifically for public safety users might not be viable)[13]

---

13 Furthermore, if the public users of the network know that in times of a local emergency they will lose the network services, this creates a disincentive for users to subscribe to that network, a risk that commercial operators are unlikely to take on.

- there is a question about whether the required Grade of Service for public safety use can be guaranteed within a network shared with commercial users, particularly in times of very high traffic loading
- there are conflicting views on whether signalling could be encrypted over the air interface in 3G/LTE
- ensuring the specific requirements for carriage of 'restricted' or 'confidential' documents requires careful network planning and approvals, which is complex and costly to achieve
- in conditions of local or national emergency, public networks typically become overloaded as the normal customer base seeks to communicate at the same time, and it is not clear that networks can be dimensioned to achieve the required immediacy and guaranteed access that public safety requires.

A further range of reasons why public safety users have been reluctant to make more widespread use of existing commercial networks, and have favoured the development of their own dedicated networks, are included in the various documents we have reviewed for this study. These include the points summarised below.

Coverage	Commercial operators typically invest in coverage where populations exist, and capacity is designed to maximise revenue generation in those areas, with little incentive to invest in areas of low-density population. Public safety, by contrast, requires ubiquitous coverage across a country's geography for everyday use, irrespective of population densities.
Network design	Re-engineering of commercial networks to meet public safety's requirements might be feasible in theory, but in practice would result in large parts of the commercial network being heavily over-engineered. This is likely to be more costly for the public sector to fund than a dedicated network provisioned to meet the specific coverage and capacity needs of the public safety user based, without having to provision for additional commercial traffic.
Sabotage	There is a view that commercial networks might be more vulnerable to sabotage by criminals that dedicated networks are, if the network is known to be used for public safety communications. Dedicated public safety networks are typically more guarded against sabotage through a range of specific measures e.g. vetted staff, secure fencing at sites, and networks designed to ensure no single point of failure in the event of sabotage, etc.).
Roll-out schedules	There are precise requirements for the roll-out of public safety networks (e.g. the need to align with police/fire/ambulance area boundaries), which do not match typical commercial roll-out strategies.
Risks of shared use	There are risks such as information security, quality of service and control of service level agreements if public safety users share networks with commercial users, which previous experience suggests can be avoided through use of dedicated networks under government control and supervision.
Reliance on commercial operators	There is a reluctance for public bodies to be reliant on a fully commercial operator, in view of the potential lack of control upon future network investment, business plans and financing.

If the upgrading and engineering of commercial mobile broadband networks is not feasible to meet public safety requirements, as this section suggests, the only alternative is to develop a new generation of dedicated mobile broadband networks designed to meet specific public safety requirements. For this to be achievable, additional spectrum will be required.

7 Conclusions

The study has found that, in line with societal trends evident within today's Information Society, a diverse range of data, imaging and multimedia applications are in demand within the public safety sector. Demand for access to a wider range of information is being driven by changes in working practices, which is creating requirements for access to a far wider range of data sources (textual, images and video) that are typical in commercial mobile networks. Sharing of various data types (textual, images, video, etc.) is being used in order to establish and maintain a common operational picture between agencies and between field and central command staff. This is being used to improve responsiveness, aid the deployment of resources, and improve timeliness and decision making in daily public safety operations and when responding to major planned or unplanned events.

Three of the four evolutionary paths developed for this study illustrate the public safety sector's need for a next generation of mobile broadband networks to deliver the range of applications that are envisaged in the future. As there is a limit to the range and volume of data and multimedia applications that existing dedicated narrowband and wideband networks, and existing commercial networks, can provide, if a new generation of mobile broadband networks is not made available, some new applications cannot be delivered. Ultimately, this will affect how already emerging changes to ways of working within the public safety might evolve, and, in the longer term, constrain the further development of the sector.

A new generation of services could in theory be delivered using an upgraded commercial network (e.g. HSPA/HSPA+ or LTE) with network deployment engineered to meet specific public safety requirements. However, as explained in Section 6.2, this option does not appear to be achievable in practice. The only other option is therefore to encourage industry to develop a new generation of mobile broadband networks for dedicated public safety use.

To enable the industry to devote the necessary investment to develop new dedicated networks, there is a need for additional spectrum to be identified, since existing bands are already fully utilised to deliver existing public safety systems.

It should be noted that identifying suitable spectrum is on the "critical path" to support development of a new generation of dedicated mission critical mobile broadband solution, because of the timescales associated with identifying suitable spectrum.

The requirements for additional spectrum are based upon the combination of the various factors identified throughout this report, specifically:

- trends in the range of data and multimedia applications in demand within the public safety sector
- potential increase in user densities and intensity of use for data applications

- specific traffic characteristics of public safety operations (e.g. network-centric ways of working)
- the infrastructure and technical requirements to meet the operational requirements of the public safety community (e.g. availability, security, reliability, latency), and limitations in use of commercial networks to deliver these.

Given the cost of deploying new networks, access to spectrum in bands below 1GHz will ensure maximum commonality with existing dedicated networks deployed in the 380–385/390–395MHz bands, facilitate re-use of assets where possible (e.g. radio sites). Use of spectrum above 1GHz (e.g. around 2 GHz) might be feasible, but would incur significantly higher roll-out costs compared to that below 1GHz, raising questions at national government level as to whether and how the additional costs can be funded.

Based on the reviewed documents, the European dimension to the public safety spectrum requirement is important for a number of reasons:

- the public safety sector is a niche market and therefore benefits from the identification of harmonised spectrum even more than other mobile systems (e.g. GSM or UMTS), because of the smaller user base and resulting lower volumes of equipment and terminals
- even if commercial solutions are adapted to meet specific requirements of a niche sector such as public safety, there are still costs involved in the necessary modifications, and therefore harmonised spectrum availability is key to ensure that manufacturers are able to develop products for a European market. An example of the re-engineering of existing commercial standards to meet niche requirements is that of GSM-R (the railways version of GSM) – although the GSM standard is supported by all major vendors around the world, GSM-R equipment is supplied by relatively few and the availability of harmonised spectrum for the product has therefore been important to reduce costs
- interoperability is an increasingly important requirement within the public safety sector, both to communicate between different public safety authorities within a country, and to communicate across borders. This is evidenced by a number of the documents reviewed for this study.[14]

The lack of available spectrum is therefore a significant barrier to the further development of mobile communications capabilities tailored to meet public safety requirements, until such time as a new, harmonised band can be identified at a European level.

14 For example, Council of the European Union, Draft Council Recommendation on improving radio communication between operational units in border areas

Annex A: List of acronyms

ANPR	Automatic number plate recognition
AVL	Automatic vehicle location
CEPT	European Conference of Postal and Telecommunications Administrations
ETSI	European Telecommunications Standards Institute
GHz	Gigahertz, 1GHz is equal to 10^9 hertz
GIS	Geographic information system
GPRS	General packet radio service
GSM	Global System for Mobile Communications, the most prevalent international standard for second-generation cellular mobile systems
GSM-R	GSM-Railway, an adapted version of the GSM standard used by Network Rail (UK) and other railway authorities in Europe to provide train-to-track signalling
HSPA(+)	High Speed Packet Access, a protocol that can form an overlay to existing 3G networks to speed up network capacity and transmission rates
ITU	International Telecommunication Union
LTE	Long Term Evolution, the next generation of 3GPP standard, which uses an OFDM radio interface – sometimes referred to as "4G"
MHz	Megahertz, 1MHz is equal to 10^6 hertz
NATO	North Atlantic Treaty Organization, the military alliance of countries in Europe and the USA
OFDM	Orthogonal frequency-division multiplexing, the air interface that is used in WiMAX systems and will be used in LTE
PABX	Private automatic branch exchange, a telephone exchange serving a particular business/office
PBR	Private Business Radio, generic term used to describe the variety of two-way, self-provided, mobile radio systems used by a variety of business users in Europe (including airports, taxi firms, local authorities and the Emergency Services pre-Airwave analogue radio systems)
PSTN	Public switched telephone network
RFID	Radio frequency identification
TEDS	TETRA Enhanced Data Service
TETRA	Terrestrial Trunked Radio, the digital trunked radio standard used by the Airwave service in the UK and in other Emergency Services mobile radio systems in a number of other countries Europe and around the world
UHF	Ultra high frequency, i.e. between 300MHz and 3000MHz
UMTS	Universal Mobile Telecommunications System, the European standard for third-generation cellular mobile systems
VHF	Very high frequency, i.e. between 30MHz and 300 MHz
WCDMA	Wideband CDMA, the technology used in current 3G systems
WiMAX	Worldwide Interoperability for Microwave Access, the technology forming the IEEE802.16e wireless broadband
WGFM	Working Group FM
WRC	World Radiocommunication Conference, the International conference held by the ITU every few years to update the international frequency allocation table
3G	Third-generation mobile systems
3GPP	3rd Generation Partnership Project, a partnership between ETSI and standards bodies in the USA and Asia, responsible for developing industry equipment standards for 3G systems

C.1 TETRA Association Future Vision Workshop (Brussels)

Item	*Description*
Document title	TETRA Association Future Vision workshop held in Brussels on 25th February 2009
Author	Various
Publication date	February 2009
Abstract	Various presentations discussing the future vision for TETRA towards a fully integrated ICT solution providing NB/WB/BB wireless communications for 'mission-critical' and traditional PMR/PAMR applications, through the enhancement and/or provision of user driven services and facilities and the utilisation of the latest in technology, innovations and standards. The workshop discussed applications including data rate, bandwidth and QoS, user requirements for broadband data, and other areas of consideration in the selection and standardisation of a broadband solution.

Requirements or needs identified in report	The need for the industry to evolve TETRA towards a fully-integrated seamless ICT solution providing NB/WB/BB wireless communications for mission-critical and traditional PMR/PAMR applications.
	Data and image applications are emerging as a strongly needed requirement to improve users' efficiency and safety.
	The fundamental requirements are:
	• Ability to communicate in all locations (100% radio coverage)
	• Instant access at all times (perfect Grade of Service)
	• Never goes wrong (100% reliability)
	• Voice and data (V+D) communications
	• Perfect voice quality in all operational environments (ability to recognise who is talking)
	• Ability to support all V+D applications
	• Private and secure communications when required
	• RF coverage in black spots and outside main network
	• Additional capacity when localised traffic demands are high
	• Fall-back communications if base station and/or network fails
	• Ability to support all non-voice applications (real-time and other)
	• Standardised technology solution providing:
	  ▪ competition
	  ▪ choice
	  ▪ second source security
	• Interoperability:
	  ▪ within the same organisation
	  ▪ within other related organisations as required (e.g. police, fire, ambulance, military, transport, utility, etc.)

- cross-border with other nations as required
- Interworking with other technologies as need (Public Networks, 3G, etc.)
- Evolution:
  - backward compatibility
  - maximum reuse of existing infrastructures
  - future proof
  - enhancement
  - integrated and seamless ICT
- Current mission-critical communication needs to be:
  - dedicated
  - wide-area
  - secure
  - reliable
  - available
  - fit for purpose.

Possible applications identified in report

Real-time applications, where source generates the information to the destination and strict constraint to delay and its variation over the network is fundamental for using the application.

Non-real time applications, where the source has the information and sends it to the destination. Source can send part of the information missing and re-order the packets.

Applications include:

- Automatic stolen car plate recognition (approx 10byte/plate required throughput)
- Biometric check
  - fingerprint required throughput per officer – check rate: 8 people/min
  - y=(8people/min) / (60sec/min) x 1kByte/People =133byte/sec = 1.06kbit/s
- Image transmissions
  - target acceptable resolution: dimension 20kByte = 160kbit/ user
- Face recognition
  - the minimum number of pixels to recognize faces is 40PPF (pixels per foot) the minimum number for reading license plates is 80PPF
- Mobile office
- Database queries
- Video surveillance from the field
- Mobile command centre sharing an accurate situation picture of an incident
- Delivering images, maps and floor plans to the field
- Detailed ECG traces from ambulance to hospital and other telemedicine applications
- Fingerprint identification/authentication
- Image/audio capture
- Geographical positioning

	• Electronic identity document reading • Voice communications • Data connectivity • Optical character recognition (OCR) • Electronic signature certificate management • Cryptography
Possible benefits identified in report	Not applicable
Can the benefits be realised using commercial networks	Not applicable
Possible scenarios identified	Not applicable
Any other relevant information from the report	Possible TEDS broadband solution: • Integration of other technologies with TETRA ▪ Use of TETRA 2 infrastructure as the core network ▪ 3G technologies such as HSPA, LTE or EV-DO, UMB ▪ WiMAX (preferably narrowest channel options at lowest designated WIMAX frequencies) • TEDS Technology Evolution ▪ Use of wider carriers than TEDS ▪ More spectral efficient channels ▪ Other features under discussion in WG4 ▪ Acquisition of new spectrum for interoperable TETRA 2 (plus BB enhancement) networks? • Other comparative considerations ▪ LTE, WiMAX and other public BB networks designed for mass market/urban applications ▪ Wider and wider carriers, smaller and smaller footprints ▪ Design criteria: capacity limited, maximum commercial return ▪ No slack capacity for emergency communications ▪ PPDR networks design criteria: coverage limited ▪ Full national coverage essential for PPDR; capacity is not an issue ▪ Narrowest bandwidth/lowest frequency band compatible with required PPDR applications and spectrum availability ▪ NB, WB and BB in the same frequency band ▪ PMR type security, availability and reliability • Operational use for video must be understood ▪ What is required in a court case (used as evidence)? ▪ What is required in emergency response? ▪ What is required for surveillance, facial, licence plate recognition?

C.2a TETRA Association Applications Workshop and mobile data questionnaire

Item	*Description*
Document title	TETRA Association Applications workshop held in London on 2nd December 2009 Mobile data applications questionnaire results
Author	Various
Publication date	December 2009
Abstract	Various presentation discussing applications for TETRA.

Requirements or needs identified in report	Security, safety, cost and service are the critical features of an optimal mission-critical data solution, along with a requirement for an integrated system that can be used throughout the response chain (i.e. services all accessible via the same terminal or device) and data services as reliable as TETRA voice.
	
	Customer specific applications that enhance the functionality or usability, versatility and productivity of the TETRA radio terminal for different purposes.
	
	Existing applications require more capacity.
	
	Ability to move office applications into the field.
	
	Operational needs: resilience; availability; security.
	• Ciphering and encryption
	• Mission critical communication
	• Availability of resources under all circumstances
	  ▪ operational even when public networks are congested
	• Resilience
	  ▪ ability to work in crisis situation (major electrical disruption, transmission network failures, etc.)
	• When all public communication infrastructure are out of order, the radiocommunications network should be kept operational.

Possible applications identified in report	Current applications:
	• Collect and share common situation picture
	• Allocate right resources efficiently
	• Distribute and obtain information instantly
	• Collect surveillance, medical, etc. monitoring information
	• Automate administrative routines
	
	Future applications:
	• Fingerprint recognition
	• Licence plate recognition
	• e-Passport reader
	• RFID reader
	• JAVA applications on TETRA terminals:
	  ▪ Access information in remote databases
	    o Vehicle databases
	    o Criminal records
	    o Hazardous materials

	▪ Report location - related information o Task progress o Intelligence information o Support requests ▪ Push images to field officers o Suspects from surveillance camera o Missing persons o High risk suspects • Streaming video ▪ Transmission of live videos simultaneously to/from the central command and field personnel ▪ Relaying ad-hoc videos and surveillance camera to the central command and field personnel ▪ Air-to-ground video • Real-time collection of large medical data ▪ Sending full data on a patient's condition from the ambulance ▪ Remote surveillance of smoke divers' vital functions ▪ Remote surveillance of patrolling officers' vital functions • Access to geographic images ▪ Aerial photographs ▪ Satellite images and maps ▪ Plans of buildings • Remote database queries for passport and biometric details • Sending photographs of lost children and wanted people • Access too the Fire service 'Gazetteer' for information on HazMats on premises • Transmission of live video to and from the central command and field personnel • Relaying ad-hoc video and surveillance camera • Sending full data on patient's conditions from the ambulance • Integrated broadband data services which are emerging as an important PSS need require more bandwidth – ideally two paired 15MHz channel • Telemedicine • Extensive geo-location capabilities • Web applications • Full email • Over-the-air downloads for software upgrades
Possible benefits identified in report	Not applicable
Can the benefits be realised using commercial networks	There are network availability issues with commercial networks, for example: • Motorway Car Crash – statistics show that the network call volumes increase during a major auto crash. People involved call loved ones, witnesses call for assistance and other drivers call to say that they will be late. What is the impact to data?

	• Major Sport Events – peak GSM/GPRS load times are before, half time and after the match = critical times for secured communications. Historically mobile telephony calls can fail during these periods
	• Natural disasters and terrorism – after the Madrid bombings; the mobile phone network collapsed at 8:05am and was out of use for eight hours
	• Public networks do not meet PS user requirements
	  ▪ Coverage, Availability, Security, Resilience, Interoperability
	  ▪ Control, Functionality
	• Public network operators are able to prioritise PS users, but
	  ▪ When the public is cut off, they call the emergency services to get information.

Possible scenarios identified	Not applicable

Any other relevant information from the report	▪ Mission critical applications can be optimised to reduce the amount of data that is transmitted over lower bandwidth wireless networks: the communication payload:
	  ▪ TCP/IP – 40bytes
	  ▪ UDP/IP – 28bytes
	  ▪ Radio optimised TCP/IP – 10 to 15bytes
	• Mobile data helps effectively to:
	  ▪ Collect and share common situation picture
	  ▪ Allocate right resources efficiently
	  ▪ Distribute and obtain information instantly
	  ▪ Collect surveillance, medical etc monitoring information
	  ▪ Automate administrative routines.

C.2b TETRA Association TEDS workshop and TWC survey

Item	Description
Document title	TETRA Association TEDS workshop held in Bonn on 27th March 2007 TWC questionnaire in 2008
Author	Various
Publication date	March 2007
Abstract	Various presentations discussing user requirements, technical specifications for TEDS, spectrum and regulatory issues and applications for TEDS.
Requirements or needs identified in report	There is a need for mission critical data and data speeds beyond the TETRA 1 narrow band service. The capacity enhancements brought by TEDS are also needed so that systems can handle the load of multiple, concurrent narrow band data services such as database access and ID-card or fingerprint verification. The usage scenario in the field seems to be developing towards a network-centric way of working that relies on personalised data and where an overview of the incident is shared, which improves the situational awareness. More and more daily routines are expected to move to take advantage of data and there is a trend towards mobile offices – activities traditionally confined to an office environment are possible in the field. Need for the "higher bit rates" in wider channels: • Higher bit rates (150–500kbit/s?) • Wider channels (150kHz?) • Spectrum (2×5–10MHz?) • Timing TIP certified product available: 2010? Need for TEDS spectrum in PSS (based on re-use factor of 20 or more): • One 50kHz layer ▪ 2×20×50kHz = 2×1MHz absolute minimum ▪ 2×30×50kHz = 2×1.5MHz reasonable minimum • Double 50kHz layer (100kHz per site) ▪ 2×20×100kHz = 2×2MHz absolute minimum ▪ 2×30×100kHz = 2x3MHz reasonable minimum Applications need to work on multiple networks to maximise available coverage area and bandwidth Key Nødnett (Norwegian PS Network) TEDS User Requirements: • Basic user requirement is for the transfer of 100KB of data (e.g. picture) from a radio terminal within 10 seconds • No specific data applications identified at this stage but rather the expectation that there will be a strong operational need for higher speed data applications in the future • TEDS upgrade must minimise any disruption to the 'live' network • Level of encryption must be at least as good as TETRA 1
Possible applications identified in report	• Personalised information • Mobile command and control – dispatching • TEDS as data only layer – voice services provided by TETRA 1

- Location tracking
- Narrow band services
    - Scanned images (ID-cards) for verification
    - Database access
- Wide band services
    - Video, both uplink and downlink
    - Messaging including attachments
    - Maps and drawings, images to vehicles
    - Remote maintenance – download of terminal configuration, firmware, software

Top TEDS data applications identified at workshop:

- Navigation / location tracking / AVL
- Database queries (medical journal lookup, simple query and image-query)
- High resolution still pictures (pictures from field, maps, fingerprint, vital data sampling)
- Instant Messaging / email / news (field-to-field and office-to-field)
- Electronic forms (paperwork, ambulance, home nurse)
- Telemetry (sensors in vehicle / on patient)
- Web browsing
- Video streaming (surveillance) and video conferencing

Possible benefits identified in report

Not applicable

Can the benefits be realised using commercial networks

No, as commercial data services cannot be expected to be available at all times.

Possible scenarios identified

Not applicable

Any other relevant information from the report

TEDS features:

- To be included in the TEDS TIP:
    - Security
    - Modulation 4/16/64 QAM
    - Service interaction
        - Voice services offered to user busy in TEDS data service
        - Concurrent voice and data
    - Quality of Service
    - TEDS PEI (MEX)
    - Multi-slot operation
    - Sectored cells (extended coverage)
    - High speed
- Additional TEDS Features which would first need standard update:
    - Multicast
- Devices:
    - Data only TEDS devices
    - Mobile and hand portable TEDS enabled voice & data devices

TEDS does not cause significant interference to other systems but TEDS cannot co-exist with military air-ground-air radios.

C.3 Analysys Mason study on digital dividend

Item	*Description*
Document title	Exploiting the digital dividend – a European approach
Author	Analysys Mason, DotEcon and Hogan & Hartson LLP
Publication date	14th August 2009 (Final report)
Abstract	This document summarises the work carried out on behalf of the Information Society and Media Directorate General of the European Commission to ascertain what action needs to be undertaken at EU level to ensure the benefits of the digital dividend are maximised, including: • conducting an inventory of the situation in each Member State regarding the digital dividend • carrying out analysis to understand the demand for the spectrum as well as the social and economic value of potential users • reviewing technical issues, such as technology trends, interference issues • developing a range of scenarios for a co-ordinated EU approach, and a cost/benefit analysis of each approach. The report identifies seven potential uses of the digital dividend – DTT, commercial wireless broadband, services ancillary to broadcasting and programme making (SAB/SAP), broadcast mobile TV, cognitive technologies, wireless broadband for public protection and disaster relief (PPDR) and an innovation reserve. The study offered a set of recommended actions for a co-ordinated approach and a proposed roadmap for implementation.
Requirements or needs identified in report	The need for high bandwidth wireless services. PPDR is widely perceived as a high-value use of spectrum and the value of this use cannot be expressed solely in economic terms, as PPDR systems are used for safety of life and are regarded as necessary government services.
Possible applications identified in report	High-speed data transfer, e.g. paramedics need to transmit medical images and or reports to colleagues ahead of their arrival at the hospital. Real-time video transmission, e.g. to improve efficiency; ability to see what is happening at the scene; and instantly collaborate with central command, co-workers and other agencies.
Possible benefits identified in report	A PPDR network would be a key asset in the development of public health services and security for all, and as such would sustain the quality of life of citizens across Europe.
Can the benefits be realised using commercial networks	Commercially available wireless broadband technologies (e.g. WiMAX and LTE) could offer economies of scale and superior handset availability but may not be sufficiently reliable as they are optimised for different objectives than PPDR.
Possible scenarios identified	Not applicable
Any other relevant information from the report	The emergency services rely on good in-building coverage in order to communicate effectively at the scenes of incidents, and so spectrum below 1GHz is particularly suited to meet their requirements. In its 2008 Communication on "Reinforcing the Union's Disaster Response Capacity" , the Commission stated that "European citizens expect the Union to protect their lives and assets inside the EU" and stated that the "challenge of disaster prevention, mitigation and response…require[s] a comprehensive

approach by the EU to the continuum of disaster risk assessment, forecast, prevention, preparedness and mitigation (pre- and post-disaster), bringing together the different policies, instruments and services available to the Community and Member States working as a team'.

Wireless broadband for PPDR (in addition to or to replace existing services) could realistically only be deployed terrestrially using spectrum below 1GHz, deployment at high frequencies would be too costly. It may be possible to deploy such a service in other bands, such as 450MHz, but less spectrum is available and it would require concerted coordination across Member States. Thus the incremental value is either (a) the additional value over and above existing national services; or (b) any extra costs or changes in service quality from using another band.

C.4 PCWG ad-hoc group studies

Item	*Description*
Document title	Police Cooperation Working Group – Improving radio communication between operational police units in border areas; analysis of the responses received to the data capture exercise on cross border working
Author	Police cooperation working group
Version	-
Abstract	Based on two documents – responses from 12 administrations to a questionnaire sent out on cross border working and a technical brief discussing the medium and long term goals for cross border emergency services mobile communications requirements following the survey. The Police Cooperation Working Group created a technical ad-hoc expert group on the future of radio-communications in July 2008, following the EURACOM seminar whose main objective is to identify technical solutions to foster interoperability between police forces, especially in border areas. The document puts together some ideas of how interoperability and cross border communications might be accomplished at a technical level and discusses a number of the issues that arise. The questionnaire addresses the requirements for voice, data, coverage, encryption requirements, spectrum and consideration of using a public network. The outcome of a three country pilot experiment in cross border communications was carried out between Germany, Belgium and the Netherlands was also presented.
Requirements or needs identified in report	• Full interoperability across Europe • Ability to create talk groups across networks • Pan-Europe direct mode capability • Ability to handle biometrics and other imagery and video-mobile broadband capability • Access to both home and local databases (this must be managed carefully with respect to security issues) • End-to-end encryption is preferred but air interface only encryption is accepted by some administrations • Full area seamless communications / interoperability across Europe (ISI?) • Border zone coverage, approx 15km • Access to both home and local control rooms (language issues will be highly significant and may be a greater obstacle then the technical issues) • Ability to create talk groups including home and visiting officers (patch functions) • Point to point calls and telephone interconnect • Automatic location capability for persons and vehicles and assets • Access to home databases and local databases for visiting officers including biometric databases • Harmonised spectrum – spectrum for mobile broadband minimum 2x10MHz, more realistic to look for 2x16MHz. Harmonised spectrum is key to providing full access across borders.
Possible applications	Voice

analysys mason

identified in report	• Full communications with home control room • Access to local force communications control room • Group based communications Data • Biometry • Video (on-line streaming) from field officer • Video (on-line streaming) to field officer • GPS position location information • Database access • Transmission of patient data, maps, building drawings • Others including SDS, SMS, status messaging, situational awareness and common picture functionality
Possible benefits identified in report	More successful and efficient cross border inter-working.
Can the benefits be realised using commercial networks	All the responses provided a consensus that public networks including GSM, 3G, etc. can be used as a backup to dedicated service and for non-critical traffic only.
Possible scenarios identified	Not applicable
Any other relevant information from the report	For a cross border mobile broadband capability European harmonised radio spectrum is an absolute requirement, as it has been for the current voice communications capability. This point needs to be clearly understood and communicated to spectrum management administrations. Failure to achieve harmonised spectrum will remove the possibility for secure and resilient cross border mobile broadband communications for the foreseeable future. A much more difficult situation is cross border communications between TETRA and TETRAPOL networks. Since TETRA is a TDMA based technology and TETRAPOL is based on FDMA the two air interfaces are physically incompatible. There would therefore be limited benefit in the development of an ISI. TETRA networks mainly provide emergency mobile communications in Europe, but there are also some TETRAPOL systems. Most operate at or close to 380/400MHz. Given the difficulties noted above it likely that full successful interoperability will only be achieved across Europe when all the participating countries are: • using a common air interface standard for voice and data • operate a minimum defined set of network features • have deployed a set of agreed configuration parameters • operating in a common frequency band. There is a requirement for the following: emergency call, individual call, group call with units on both sides of a border, duplex individual calls to telephone networks (telephone interconnect), fast set up for group and point to point calls. As countries develop their mobile communications services new technologies are likely to be introduced. The UK is in the process of commissioning the Future Communications Programme (FCP) to replace the Airwave TETRA network for both voice and data communications. No decision has yet been made on the technology to be deployed. FCP will start to enter service from 2014. Cross border issues will need to be considered from the outset of the commissioning process for new networks.

Full interoperability should imply access to local control rooms and the ability to create talk-groups across networks. Effectively this suggests the formation of a super network of interconnected networks. Thought needs to be given to the creation of a standard feature set and the management of this super network capability including issues of confidentiality and national security.

A three country pilot experiment in cross border communications was carried out between Germany, Belgium and the Netherlands. The outcome:

- Four pilot groups were available however, it was not possible to select a national group in a foreign network and it was not possible to indicate which network the terminal was registered
- Emergency calls were transferred to the selected (international) group and audio could be heard by all dispatchers and radios in the three networks within this selected group
- Emergency call signalling was only possible in the network in which the call was initiated, signalling was not transferred to the other networks.
- Possible to make an individual call to another radio when both radios were registered in the same network. The reason for this is that signalling was not being transferred to the other foreign networks.
- Telephone call was supported, however the set up of a telephone call was different for each network.
- Fleetmap – each subscriber that wanted to migrate to another network needed to have a unique ITSI that was not used in the foreign network. In other words, the ITSI needed to be known and equal in all three networks. This was similar for groups and the corresponding GSSI's.

C.5 ETSI SRD on Public Safety and Security (PSS) Systems

Item	*Description*
Document title	TR 102 628 - System Reference Document; Land Mobile Service; Additional spectrum requirements for future Public Safety and Security wireless communications systems in the UHF range
Author	ETSI
Version	V1.1.1 (2009)
Abstract	This document describes the spectrum requirements of future PSS communications for wideband and broadband applications. The document refers to narrowband and wideband PPDR applications in Europe being covered by TETRA Release 1 and TETRA Release 2 (TEDS), but that there is a need for interoperable, secure and wide-area communications for public safety users for wideband and broadband applications. This cannot be accommodated in existing spectrum available to PSS users since that spectrum is already fully used by voice traffic and some data usage. The document summarises spectrum requirements of 2 separate contiguous blocks of 10 MHz plus two separate non-contiguous blocks of 6 MHz dedicated to PSS and harmonised across Europe; the total of 16 MHz for each direction to fit within a tuning range. The required frequency range is between 300 MHz and 862 MHz, preferably in the lower parts of the band. The document advocates allocation of a dedicated spectrum band for harmonised wide-area communications capable of high-speed IP based data applications. Spectrum should be sufficient to meet the requirements of day-to-day PSS traffic and also cater for peak usage during major incidents
Requirements or needs identified in report	▪ Mission critical PPDR communications are exhibiting an urgent and growing need for inter-operable high-speed data services. ▪ The wideband ECC Decision for 380-470 MHz does not give the PPDR community extra data capability, since the actual spectrum available is insufficient to accommodate high speed data applications ▪ Lack of further availability of spectrum will risk the future development of the PPDR community through inability to support new services requiring more data (e.g. identify cards, photographs, fingerprints), failing to keep pace with societal developments where society is increasingly adopting advanced data applications, and inability to manage major disaster scenarios efficiently ▪ User communities have determined that mobile data is equally as missions critical as voice, and therefore cannot be safety transported over commercial mobile networks. This is because officers will become more and more reliant and dependent on mobile data communications in support of their day-to-day operations ▪ PSS TETRA networks will start being replaced, at least in part, from around 2012 onwards, with new technology needed to support voice, narrowband, wideband and broadband data services and be backward compatible and interoperable with existing (TETRA) networks ▪ Spectrum requirement includes one contiguous component of at least one broadband channel width (10 MHz). Split of spectrum or fragmented spectrum is not viable due to RF front end complexities and difficulties with interoperability ▪ Specific public safety operational requirements include control over security implementation and other operational aspects of the network, redundancy of components on cell sites (e.g. transceivers, site controllers, antennas), redundancy of UPS power supply capability,

including battery and generator powered supplies, a high degree of network resilience (e.g. overlapping coverage from multiple cell sites), fallback strategies to allow stand-alone operation of sites disconnected from the rest of the network, redundant switching and a high level of RF coverage

- DMO is required in all radio terminals, plus availability of the associated repeaters and gateways to provide RF coverage in difficult areas or where base station coverage has been lost
- Need for fast communications set-up in combination with a much higher call set-up success rate, typically 99% or even higher for PSS compared to what is offered by public networks

Possible applications identified in report

- At present, operational PSS networks support voice and narrowband data services only. Whilst those applications will continue to be required, others that are needed include video conferencing, video streaming, full satellite navigation, secure passport and bio-metric checks, online access to various databases, full email internet browsing, and improved transfer of files (including maps and pictures)
- Ability to move the back office into the field
- Sending detailed photographic images of lost or wanted people
- Relaying ad-hoc video camera and surveillance camera real time information to patrol cars
- Sending detailed maps and plans
- Sending biometric data from an incident in real time, rather than having to return to the office
- The ability to transfer video data back to incident commanders to make faster and more informed decisions
- Cross-departmental communications
- References data service attributes from ETSI TS 102 181 of email, imaging, digital mapping, location services, real time video, slow scan video, remote database access, database replication and personnel monitoring

Possible benefits identified in report

- Socio-economic benefits include: saving lives of citizens and public safety officers, minimising damage to properties, faster response, more efficient communications, enhancement of a single emergency communication network with high reliability, availability and security, better co-ordination between different public safety organisations and agencies both nationally and over borders
- Potential to enhance investments in European national public safety infrastructures through evolutionary enhancement
- Single wide-area coverage network resulting in major cost savings in the network infrastructure compared to use of multiple solutions
- Creation of a pan-European or global harmonised set of equipment requirements, resulting in higher economies of scale and lower costs.

Can the benefits be realised using commercial networks

- The mandatory services and facilities required by public safety organisations can only partially be provided on networks designed for commercial use, since those networks cannot be used to carry mission critical traffic
- In many commercial networks, data is sent at lower priority than voice, which could be a significant problem for public safety users who often find themselves in areas where voice services are being used intensively, but that data services are also needed

	• Even if a commercial network was designed to meet the operational needs of public safety users – i.e. resilience, QoS, security – many Governments would still need to ensure that ownership of the operator would be under Government control, or alternatively may require continued guaranteed financial viability and/or options to take management control of the network when needed
Possible scenarios identified	• Large fire encompassing 3-4 blocks in a large city or a large forest fire • Large public event e.g. Commonwealth Heads of Government Meeting, G8 Summit, Olympics • High-resolution video communications from wireless clip-on cameras to vehicle-mounted laptop used during traffic stop or response to other incidents, and video surveillance of security entry points such as airports with automatic detection based on reference images, hazardous materials or other relevant parameters • Remote monitoring of patients and remote real-time video view of the single patient
Any other relevant information from the report	• Annex A.2 refers to recent survey conducted by Motorola and APCO of more than 200 public safety administrators and officers in the top 100 US markets regarding current and future use of communications • Annex B.2 refers to technology evolution e.g. narrowband-wideband-broadband

C.6 Results of the questionnaire on PPDR prepared by ERO on behalf of CEPT WGFM PT38

Item	*Description*
Document title	FM38(09)15 Rev 2 Annex 3, Result of Questionnaire on Public Protection and Disaster Relief
Author	CEPT European Radiocommunications Office (ERO) on behalf of CEPT Working Group Frequency Management (FM), project team 38 (FM38), with responses from spectrum authorities, PSS users and industry
Version	Questionnaire issued February 2009, results April 2009 Contained in zipped file ERO_401925899884269
Abstract	The questionnaire was prepared by CEPT WG FM38 and issued to CEPT spectrum authorities/regulators to gather information concerning future mobile radio applications, and associated spectrum requirements, associated with Public Safety and Disaster Relief (PPDR) – also referred to as Public Safety and Security (PSS). Spectrum authorities that participate in the FM38 group were asked to forward the questionnaire to public safety users within their countries (i.e. police, fire and ambulance authorities) and invite them to respond to the questionnaire too. The questionnaire had two purposes (i) to collect information from users to clarify the user requirements and needs for mobile radio applications for PPDR (ii) to invite authorities/regulators to consider possibilities to identify additional spectrum for public safety use, and candidate bands below 1 GHz. 52 replies received – 23 from authorities/regulators, 19 from user organisations and 10 from industry.
Requirements or needs identified in report	Current applications will continue to be required in future, along with a range of new applications, with increasing emphasis on: • Broadband (e.g. real time video surveillance, including live CCTV images and images captured and relayed from helicopters) • Enhanced graphical data exchanges • On-site expert medical support • Situational awareness at fire incidents, to inform control/field decision making • Giving the officer in the field in charge of a major incident the same functions as an operator in the control room ("taking the control room out into the field") • Remote situational assessment and control • Automatic facial recognition • Much higher data rates for database querying, geo-location etc. • Mobile office • Licence plate checks.
Possible applications identified in report	All present applications (listed in table below) also required in future, along with increasing emphasis on much higher data rates to improve efficiency of current applications, mobile control room, mobile office, video surveillance.
Possible benefits identified in report	1. Many of the companies who produce TETRA equipment are based in the UK and therefore the UK export market has benefited from the harmonised development of the TETRA standard 2. Vital for national security reasons

Can the benefits be realised using commercial networks	PSS users have specific operational requirements that public networks cannot deliver: • Resilience – overlapping cell coverage, redundancy of components, multiple backhaul links from individual radio sites, resilient switching (adjacent cells to be connected to different switches), fall back sites, power standby, etc. • Commercial networks do not offer professional radio oriented services (e.g. semi-duplex voice transmission for group calls, direct mode, different user priority levels and pre-emption) • Lack of security with commercial networks • In some countries there are limitations relating to the ownership/share structure of operating companies providing secure Government communications, which prevents use of commercial operators
Possible scenarios identified	Not applicable
Any other relevant information from the report	Questionnaire responses confirm PSS users currently use a mix of dedicated and commercial systems across Europe (TETRA, TETRAPOL, commercial GPRS/3G,satellite, RFID). Emphasis in future is integration i.e. simultaneous voice and video over the same network.

C.7 Results of the TC-RSS WG4 questionnaire

Item	*Description*
Document title	ETSI TR 102 733 and ETSI TR 102 734, Re-configurable radio systems (RSS): System aspects for public safety and user requirements for public safety
Author	ETSI TC TTS WG4
Version	V0.0.12 (November 2009)
Abstract	ETSI technical reports referring to a feasibility study of the system aspects (703) and requirements (704) for re-configurable radio systems (i.e. cognitive technologies etc.) for public safety. It identifies and defines the requirements of RRS to the public safety domain, incorporating the results of a questionnaire distributed by ETSI TC RRS WG4 to end-users across Europe. The scope refers to re-configurable radio systems only, and does not define requirements/system requirements for a complete radio replacement system for public safety users.
Requirements or needs identified in report	Defines the role of different public safety authorities, e.g.: • Law enforcement – patrolling to identify and intervene in cases of offence to criminal law, criminal investigation, customs verification, law enforcement in the transportation domain (air, road, rail, sea), custody and transportation of criminal convicts • Emergency medical and health service – provide critical and supportive care of sick and injured citizens and the ability to transfer citizens in a safe and controlled environment. Information required by EMS providers includes patient information, medical information, resource information, incident information and geographical information • Border security (including coast guards) – verification of illegal immigration, verification of the introduction of illegal substances, verification of introduction of goods in offence to customs regulations • Fire-fighting – including fire fighting, search and rescue, management of hazardous materials, protecting the environment, salvage and damage control • Protection of the environment (forests etc.) – typically employing sensor devices • Search and rescue • Crisis management – typically requiring situational information/situational awareness. Requirements defined as: joint operations between different PSS users, ability to operate in unpredictable conditions, ability to communicate when networks are unavailable (i.e. direct mode), terminals interoperability, limited budgets, security of various levels, resilient networks, resource management (i.e. support dynamic prioritisation of available capacity) and scalable networks From the user survey (RRS WG4 questionnaire), the following requirements are identified: • Broadband connectivity • Interoperability between different PS users • Avoid need to use multiple terminals • Communications in tunnels/underground/indoors • Increased capacity, coverage, grade of service, voice quality, robustness

	to interference, reduced call set up time. • Messages of large sizes, access to databases, access to web, video, video conferencing, distribution of images and buildings plans, medical information, bio metric data, weather/traffic information, software updates to terminals in real time.
Possible applications identified in report	1. *Verification of biometric data.* Public Safety officers may check the biometric data of potential criminals (i.e. fingerprints facial/iris recognition) during their patrolling duty. The biometric data could be transmitted in real-time to the headquarters or a center with the biometric archives and the response could be sent back to the Public Safety officers. This would be a positive method of identification during field interrogation stops. 2. *Wireless video surveillance and remote monitoring.* In these types of applications, a sensor (fixed or mobile) can record and distribute data in video-streaming format, which is then collected and distributed to public safety responders and command & control centers. 3. *Automatic number plate recognition where a camera captures license plates and transmits the image to headquarters* or a center with the plate data to verify that the vehicles have not been stolen or the owner is a crime offender. 4. *Documents scan.* In patrolling or border security operations, public safety officers can verify a document like a driving license in a more efficient way. Documents scan is also useful in border security operations where people, who cross the borders, may have documents in bad condition or falsified. 5. *Database checks.* This application area includes all the activities where public safety officers must retrieve data from the headquarters to support their work. 6. *Location/Tracking for Automatic Vehicle/Officer Location.* The public safety officer has a GNSS position localizer on the handheld terminal or the vehicular terminal. The positions are sent periodically to the headquarters so that the command centre can organized and execute the operations in a more efficient way. 7. *Transmission of Building/Floor plans and Chemical data.* In case of an emergency crisis or a natural disaster, Public Safety responders may have the need to access the layout of the buildings where people may be trapped or where dangerous chemicals are kept. Chemical data, building or floor plans can be requested to the headquarters and transmitted to the public safety responders. 8. *Monitoring of Public Safety officers.* Vital signs of Public Safety officers could be monitored in real-time to verify their health conditions. This is particularly important for firefighters at fire incidents and officers involved in search and rescue operations. 9. *Remote emergency medical service.* Through transmission of video and data, medical personnel may intervene or support the team in the field for an emergency patient. 10. *Sensor networks.* Sensors networks could be deployed in a specific area and transmit images (thermal) or data to the Public Safety responders operating in the area or to the command centre at the headquarters.
Possible benefits identified in report	Not applicable
Can the benefits be realised using commercial networks	PSS requirements capture routine operations, emergency crisis, major planned events, natural disasters and search and rescue – all of which require ubiquitous communications, and the ability to concentrate capacity in incident areas, which commercial networks do not provide. Lack of network

capacity is mentioned as a key problem during emergency incidents.

The document also cites the following reasons (these relate to why PSS requires re-configurable radio systems in addition to voice/data wide area networks to overcome the limitations of existing public safety communications systems in large incident situations, but some are also valid reasons against use of commercial networks):

The locations where emergency and disaster relief operations occur are unpredictable and the availability of communications facilities is not guaranteed in the incident area.

Even if wireless communications infrastructure exists in the incident area, the first responders may not have the appropriate terminals.

Public safety responders need wide area coverage, e.g., in the event of natural disasters like earthquakes or flooding, where a large area may be affected. Support for wide area coverage and higher transmission output is a conflicting requirement with low power consumption and extended battery life for handheld terminals.

Public safety organizations must operate in uncertain conditions and difficult environments both from a physical as well as from a radio propagation point of view, due to the presence of radio interferences or obstacles (man-made or natural).

Public safety responders have special requirements regarding reliability, responsiveness and security of their communication systems.

Possible scenarios identified

Refers to four scenarios contained in SAFECOM document from US communications programme of the Department of Homeland Security – Public safety statement on requirements for communications and interoperability:

1. Emergency Medical Services (EMS): Routine Patient Services and Car Crash Scenario. A voice conference call is set up between the ambulance and the hospital, while the vehicle's geo-location as well as the vital measurements and treatments of the patient are recorded and transmitted wirelessly.

2. A residential fire scenario: as in the first scenario, geo-location and vital measurements of multiple victims, first responders and vehicles is wirelessly transmitted; additionally, GIS information on building plans, fire hydrant locations, etc is accessible.

3. A traffic stop scenario: the situation message, the police vehicle's ID and geo-location are transmitted; the suspect car's license plate is read and sent to dispatch, where it's queried against several law enforcement databases, and the results are sent back to the police officer; a video stream of the action is available on demand to dispatch; the officer decides to request backup, the nearest vehicle is located by the backup system and the request is forwarded; when the suspect is arrested, information about the crime, the police officer, etc is loaded onto the RFID embedded in the handcuffs; after the arrest, biometric data from the suspect is sent to dispatch, queried against databases, and the answers are sent back; the officer communicates with the tow truck company; evidence and other information is transmitted to the sheriff's office; the case report is sent electronically to the officer's supervisor.

4. An explosion scenario: here the communications analysis is from the incident commander's point-of-view, while all the first-responder requirements described in the previous scenarios are still considered valid; the various (diverse) units that arrive on the scene form an ad-hoc overlay network and provide information about their location and status; GIS information is available on demand to the commanders; distributed sensors

	on the first-responders relay their readings to central command; a secondary perimeter is set up, and a reverse 911 call is sent to fixed and mobile users (civilian) inside the perimeter to evacuate or find shelter; at the same time, the Department of Transportation is notified to divert traffic from the area; critical infrastructure (gas, electricity) is shut down; the commander decides the explosion is not an accident, and directs field agents to treat it as a crime scene, while calling in detectives to investigate; the number of casualties is assessed too high for local hospitals, so coordination with other medical centers is necessary; at the end of the incident all-but-one of each type of team is released.
Any other relevant information from the report	The two ETSI TR refer to various other documents upon which requirements have been based: ETSI TS 102 181 (**EMTEL**) requirements for communication between authorities/organisations during emergencies TS70.001 – Service specification group services and applications Project MESA: Service specification group statement of requirements SAFECOM, Department of Homeland Security – public safety statement of requirements for communications and interoperability ETSI TR 102 182 – requirements for communications from authorities during emergencies Project OASIS – European disaster and emergency management system WIDENS (wireless deployable network system) – supported by EC IST Framework programme 6. Builds upon MESA statement of requirements.

C.8 Results from the expert group on police cooperation

Item	Description
Document title	Draft Council Recommendation on improving radio communication between operational units in border areas
Author	Council of the European Union
Publication date	20 May 2009
Abstract	The paper discusses recommendations on improving radio communications in border areas and more effective cross-border cooperation including interoperable radio communication systems in border areas and between operational services from different Member States. Difficulties in the use of radio communications in border areas are caused mainly by the lack of interoperable interfaces between current systems, which prohibit effective roaming; needs to be addressed. Therefore, significant improvement in voice and low-speed data interoperable capability could be achieved by interconnecting systems where possible. In the long term, law-enforcement and public-safety radio communication systems will need to support and to be able to exchange high-speed mobile data information. However, current law enforcement, public-safety and public networks may not be able to support this. The document recommends that: • Intersystem interfaces be developed and encourages the European Commission to provide funding for them • CEPT / ECC be tasked to study the possibility of obtaining sufficient additional frequency allocation below 1GHz for the development of future law-enforcement and public-safety voice and high-speed data networks; • European standardisation bodies be invited to start producing a European standard satisfying law-enforcement and public-safety services' operational requirements regarding high-speed data communication and roaming functionality in the medium term • In the long term, after the life cycle of current TETRA and TETRAPOL systems has ended, voice and all data functionalities (high and low speed) be integrated in a tightly integrated solution that provides a migration path including interoperability from existing law enforcement and public-safety systems to the new solution • Member States allocate additional frequencies at national level in a coordinated timeframe in cooperation with CEPT • Member States adopt any appropriate local measures in the short and medium term to improve cross-border cooperation.

Requirements or needs identified in report	• A common network standard or standards operating in harmonised frequencies to facilitate fully interoperable communications;
	• Taking into account investments in existing systems, significant improvement in interoperability in border areas can be achieved as follows:
	  ▪ in the short term, countries with common borders can work together to improve communications with local solutions;
	  ▪ in the medium term, current law-enforcement and public-safety mobile communications systems need to be connected to provide a more effective solution for cross-border communications and facilitate roaming;
	  ▪ in the longer term, a solution for mobile broadband data is required.

	A common standard operating in a harmonised frequency band will make this possible • existing frequency allocations for law-enforcement and public-safety networks may not be sufficient for the development of dedicated infrastructures satisfying operational requirements for high-speed data communication; • there may be opportunities below 1 GHz, to acquire new harmonised spectrum; • In discussing possible additional frequencies, account should be taken of the investments in current networks and also of the increased overall demand for radio spectrum and the fact that it is a scarce resource.
Possible applications identified in report	Not applicable
Possible benefits identified in report	Improve cross border cooperation between operational services
Can the benefits be realised using commercial networks	This was not discussed in length but did mention that current public networks may not be able to support and enable high-speed mobile data information exchange.
Possible scenarios identified	Not applicable
Any other relevant information from the report	Not applicable

C.9 Project MESA

Item	*Description*
Document title	Project MESA; Service Specification Group – Services and Applications; Statement of Requirements (SoR)
Author	MESA
Version	MESA TS 70.001 V3.3.1 (March 2008)
Abstract	Public Safety Partnership Project (PSPP) produced this Technical Specification (TS) during the course of Project MESA (Mobility for Emergency and Safety Applications). It describes the services and applications, which a future advanced wireless telecommunications system should be able to support in order to realize the most effective operational environment for the Sector. Emphasis has been placed on those applications, which current applied technology cannot carry out to the full, but which have been identified by the users and their agencies to be key requirements and capabilities, providing a profile of the common operational and functional requirements of next-generation aeronautical and terrestrial-based, mobile and fixed systems. The document reflects the requirements of public service and public safety agencies to have priority service and system restoration, extremely reliable service, and ubiquitous coverage within a user's defined service area. The document is intended to be a unique source of information in the aim of understanding the often very difficult and dangerous working environments, which the user community is facing, such that industry can provide the most effective and accurate technical solutions. It establishes an understanding that the advanced needs of the PPDR Sector should be based on a high-mobility, broadband wireless network or related capabilities that allow for the provision of dynamic bandwidth, offering of self healing characteristics and secure network access. Project MESA SoR also reflects the vision of a mobile broadband-shared network that can be simultaneously accessed by multiple users, with multiple applications in a specified geographical area fully independent from availability of public networks and supply of electrical power.
Requirements or needs identified in report	These include but not limited to: • Improvements in spectrum efficiencies. • Incorporation of frequency neutrality and/or agility. • Life-cycle procurements. • Security requirements. • Economical and ergonomically friendly design. • Digital migration in place. • Consistency with existing standards. • Compatibility with multiple international standards. • Two-way communication. • Multiple levels of security. • Multiple levels of availability of service. • End-to-end network integrity. • High-speed, error-free service. • System and network access. • Compliance with the need of the participating nations.

Possible applications identified in report

Wireless data requirements include such uses as mobile computing terminal applications, geographic position and automatic location data, emergency signals, transmission of reports, electronic messaging, home incarceration monitoring, and perimeter and vehicle alarms.

Multimedia systems employing both photographic and fingerprint transmission in conjunction with report automation.

Remotely controlled radio devices are routinely used for turning on and off surveillance microphones, activating kill switches in vehicles, arming and disarming alarm and monitoring systems, and aiming video cameras. This control can be a one-time data burst or can be a continuous data stream.

Unattended electronic sensors/monitors, for border surveillance, parolee monitoring and other remote-sensing technologies.

Global location services for vehicle and personnel tracking, security, and inventory control

Institutional monitoring such as remote electronic monitoring devise for house arrests and *environmental monitoring* such as real time monitoring of public resources, such as water flow and quality

Telemetry systems may also provide both an inventory of remaining infrastructure and the control of moving fixed assets, such as fire trucks, snow ploughs, police cars, ambulances, and many other types of equipment used in emergency response, including changeable signs and traveller information radio systems, as well as weather and road condition data transfer from remote sites.

Personal location device to track the location of an assigned individual for general management purposes and in the event of an emergency.

Transmission of forms and reports to central sites from mobile and remote locations. This capability will be used to transmit long data streams to and from central locations and the field in just a few seconds.

Video capabilities (real-time and close to real-time) including traffic surveillance, disaster relief, emergency medical services video, point-to-point and broadcast, transmission of videos from field operatives to command and control as well as the other way.

Robotic devices for hazardous material and explosive disposal, which require full-motion video that can be transmitted over a short distance (up to 1000 meters), from the control device to the robotic devices. This application may require the use of equipment and technologies developed for explosive atmospheric conditions and/or that will not initiate the explosive device being rendered safe.

Lifeguard/water safety personnel often require the support of robotic devices in underwater search and rescue operations, especially when persons, planes, and ships are submerged in water depths greater than 200 feet.

Possible benefits identified in report

Not applicable

Can the benefits be realised using commercial networks

The Project MESA SoR reflects the need for a network that is fully independent from availability of public networks and supply of electrical power that satisfies the following requirements:

- Transparent and seamless wide-area network applications.
- Include multiple levels of security and data encryption schemes that may be a function of the network or a function of the application or communication device to ensure end-to-end data protection.
- Offer robust operational management and control systems capabilities.

	• Reflect the requirements of MESA users to have priority operational services and priority system restoration. • An extremely reliable service model and ubiquitous coverage within a user's defined service area.
Possible scenarios identified	Describes a number of details scenarios in pages 40-43 of the document: • Law enforcement – Court house murder • Law enforcement – U.S. State and Urban Police Response to Earthquake Damage.
Any other relevant information from the report	The document includes a detailed statement of specific/unique requirements for the different government and emergency services organisations, giving examples of application needs - some of which are typically not supported in commercial terminals, which supports the argument about the requirement for dedicated networks (and associated terminals).

C.10 Toia Report on Digital Dividend

Item	*Description*
Document title	Extract: Toia Report on Digital Dividend/2008-09-26 - Text adopted
Author	Rapporteur - Patrizia Toia
Version	24 September 2008
Abstract	European Parliament resolution of 24 September 2008 on reaping the full benefits of the digital dividend in Europe: a common approach to the use of the spectrum released by the digital switchover (2008/2099(INI)).
Requirements or needs identified in report	Confirms the societal value of public safety services and the need to include support for their operational requirements in the spectrum arrangements arising from the reorganisation of the UHF band resulting from the switch-off of analogue services. Considers that the part of the harmonised spectrum at Community level dedicated to emergency services should be capable of providing access to future broadband technologies for the retrieval and transmission of information needed for the protection of human life through a more efficient response on the part of the emergency services.
Possible applications identified in report	Not applicable
Possible benefits identified in report	Societal value
Can the benefits be realised using commercial networks	Not applicable
Possible scenarios identified	Not applicable
Any other relevant information from the report	• Recognises that the increased spectrum efficiency of digital terrestrial television should allow for around 100 MHz of digital dividend to be re-allocated to mobile broadband and other services (such as public safety services, radio-frequency identification and road safety applications) whilst ensuring that broadcasting services can continue to flourish • Acknowledges that coordination at EU level would encourage development, boost the digital economy and allow all citizens affordable and equal access to the information society • Calls on the Members States, whilst fully respecting their sovereignty in this regard, to analyse the impact of the digital switchover on the spectrum used in the past for military purposes, and, if appropriate, to reallocate part of that specific digital dividend to new civilian applications • Emphasises the contribution that the digital dividend can make to the provision of enhanced interoperable social services, such as e-government, e-health, e-vocational training and e-education to citizens, in particular those living in less favoured or isolated areas, such as rural and less developed areas and islands • Encourages Member States to consider, in the context of allocating white space, the need for unlicensed open access to spectrum for non-commercial and educational service providers and local communities with a public service mission • Emphasises that Member States may consider technology-neutral auctions for the purpose of allocating frequencies that are liberated because of the digital dividend and making those frequencies tradable; considers, however, that this procedure should be in full compliance with ITU radio regulations, national frequency planning and national policy

objectives in order to avoid harmful interference between services provided; warns of spectrum fragmentation which leads to the sub optimal use of scarce resources; calls on the Commission to ensure that a future coordinated spectrum plan will not create new barriers to future innovation

- In order to achieve a more efficient use of spectrum and to facilitate the emergence of innovative and successful national, cross-border and pan-European services, supports a coordinated approach at Community level, based on different clusters of the UHF spectrum for uni-directional and bi-directional services, taking into account the potential for harmful interference arising from the co-existence of different types of networks in the same band, the outcomes of the ITU Geneva RRC 06 and WRC 07 and the existing authorisations.

C.11 WIK Study

Item	*Description*
Document title	Safety first – Reinvesting the digital dividend in safeguarding citizens (WIK_white paper_full_final)
Author	WIK Consult
Version	Bad Honnef, 5 May 2008
Abstract	Report produced by WIK and Aegis Systems with input from selected public safety organisations, regulators and TETRA vendors. The report recommends that public safety users require dedicated networks because of the unique technical and operational requirements associated with providing mission critical communications, which are extensive coverage (e.g. excess of 99% geographic coverage), capacity (e.g. public safety networks have to be capable of nationwide call set up with latencies of less than 0.5 seconds), reliability (99.999%) and redundancy (e.g. 1+1 or 1+n redundancy, power supply redundancy is essential, etc.). The report goes on to suggest that sub-1 GHz spectrum is required for public safety networks in order to meet their technical and operational requirements. Suggests that there is a 'moral obligation' to assign spectrum to public safety since PSS services are indispensable. Since emergency response ranges from routine to extreme, might be possible to use some novel spectrum allocation methods e.g. pre-emptive spectrum assignment, to provide a 'core' band for PSS use and additional spectrum that can be used when required – but when not required, can be used for commercial systems. Possible for commercial users to share a PSS networks, but not vice versa (other than for non-mission critical applications) due to the cost, complexity and risks associated with upgrading a commercial network to achieve the ubiquitous coverage, reliability, redundancy and capacity that PSS networks require.
Requirements or needs identified in report	Mission critical applications have unique technical and operational requirements, which are not met by commercial networks, since the latter are optimised for financial return on investment. They require dedicated spectrum and control of their own networks because of the flexibility it affords and ability to meet their own specific requirements of security, robustness, immediacy of communications. Public safety users have different requirements with respect to user terminals compared to commercial users – typically public safety terminals need to be designed for use and support for 5-6 years (as opposed to 1-2 for commercial handsets), due to budgetary considerations, training requirements and reliability. All handsets must have the same user interface and all operate in the same way. Mission critical refers to information that must be transmitted because it is crucial to the successful resolution of the emergency operation, requiring: coverage everywhere, instant access to resources, fixed and deployable networks, ability to support mixed traffic, flexibility, security, resilience, and additional network operation e.g. peer to peer/DMO (terminal to terminal communications without connection via the infrastructure).
Possible applications identified in report	• Remote checking of information such as passports and biometric details • Sending detailed photographic images of children lost or people wanted to officers in the field, so they can act on requests immediately • Providing access to Fire Service 'Gazetteer' which is document containing information on which hazardous materials might be kept in particular premises

	• Transmission of live video information from an incident to central command and control, so they have access to the same images as those in the field (and thereby improve decision making) • Relaying ad-hoc video and surveillance camera real time information to patrol cars responding to incidents • Sending of full data on a patients condition from the ambulance to the hospital • Video streaming (e.g. CCTV on scene) • Online access to contacts database • Email and Internet • Ability to move the back office into the field • Real time evidence collection • Licence plate recognition • Traffic light sensors.
Possible benefits identified in report	• Improved establishment of command and control – public safety agencies are increasingly moving to field command (although command and control rooms will still remain) • Dissemination of timely information (e.g. medical records, details of dangerous substances, maps, pictures and videos) • More timely response e.g. able to act on requests immediately • Better decision making – those in command and control and in the field have access to the same information at the same time • Interoperability - possibly public safety interoperability can be achieved using DMO only • Better mobilisation of teams and people • More frequent updates on emergency situational reports • Better preparation (e.g. informing hospitals of likely numbers of casualties and the sorts of treatment required) • Better incident provision from the incident area • Voice is still the central means of command and control for public safety, but they are increasingly using data applications • Better 'location' information e.g. location of fire fighters and people within a building, real time viewing of building plans, better ability for incident commander to take decisions such as building evacuation (e.g. if building is about to collapse) • Real time structural awareness.
Can the benefits be realised using commercial networks	The two main problems with using commercial networks for safety critical applications are availability and performance. Cost to upgrade a commercial network to provide the operational requirements public safety need in terms of resilience, redundancy, capacity and coverage needs to be borne by public sector since it is not commercially viable. Problems of public safety users relying on a commercial network operator include: risk of commercial operator becoming insolvent, risk of commercial operator imposing unexpected price increases, meeting specific information security requirements etc. Having a dedicated network allows public safety users to have control over QoS, SLAs etc. (possible that operation and maintenance could be outsourced to a private company). Current commercial networks do not provide 0.5 second call set up, nor

	99.999% reliability, nor power supply redundancy.
Possible scenarios identified	The report refers to a case study of the Buncefield fire – the explosion of the UK's fifth largest fuel distribution depot in Hertfordshire. Explosion took place on a Sunday when public networks were not being extensively used and in area of low population density, and so public safety users were able to make use of GSM/GPRS on that occasion – no need to ask for priority access to the network on that occasion. Problems in obtaining good voice clarity across all of the incident area were experienced.
Any other relevant information from the report	Annex D of the report summarises its main arguments and counter arguments.

C.12 PSC Europe response to the digital dividend

Item	Description
Document title	PSC Europe response to the digital dividend hearing
Author	PSC Europe
Publication date	11 June 2008
Abstract	It is a summary of the response provided by PSC Europe.
Requirements or needs identified in report	ETSI has been developing a system reference document. That document, in its current form, concludes that 2 times 15 MHz would be a reasonable amount of spectrum for the new services. However, there are other applications that would require more spectrum. This figure has been developed by ETSI and communicated to the CEPT.
Possible applications identified in report	Not applicable
Possible benefits identified in report	Value should be considered as judged by the end user and the value to citizens and society, as the value for society is not merely economic but includes important social benefits, and will place a high value on the prevention of accidents and/or the rapid handling of incidents that do occur. Generated value is something beyond just the economic value. Total value cannot always be quantified in economic units. Economies of scale – with European PS Agencies, we have a market size of only a few million devices. Harmonization will therefore have huge impact on prices and therefore the industry and the tax payers Cross-border cooperation – as demanded under the Schengen Agreement. As many EU Member States have common borders with several other Member States and therefore many operations or emergency interventions in common, cross-border operation is a vital component of emergency service provision now and in the future.
Can the benefits be realised using commercial networks	No, as public safety: • Needs an infrastructure that is independent from the common commercial networks • Needs an optimised design to carry out group calls (voice, video and data multicasting) • Needs quick connections • Needs independence • In practice, the commercial operators do not accept to grant pre-emptive priorities to the PS agencies.
Possible scenarios identified	Not applicable
Any other relevant information from the report	The combination of: • operational cross-border requirements, • economic benefit to governments and the funding taxpayers via volume effect on unit cost and • facilitation of industry business case in this limited volume but high-tech market, form a package with overriding justification that allows the EC to proceed with e.g. specific mandate or other appropriate measures. Both for operational cross-border cooperation reasons and for economic reasons that help both the investing taxpayers and the industry to build reasonable business case, harmonised frequency arrangements for the PS Services would permit the emergency agencies to deploy data services in an economically feasible way.

C.13 EULER End User Requirement

Item	*Description*
Document title	EULER End User Requirements Deliverable 2.3-1
Author	Dimitrios Symeonidis
Version	V0.8 (September 2009)
Abstract	The objective of EULER (European Software Defined radio for wireless in joint security operations) is to answer the operational question of how a major civil international crisis can be rapidly resolved jointly given the various types of radios used by different national emergency services. The end user involvement package is organised around a framework for usage scenarios and requirements and systematic methodology for the harmonisation of needs at the European level. The document summarises the End-user involvement framework definition and lists past projects, where the conclusions are summarised and the methodology for requirements classification, requirements harmonisation and matching of the EULER scope are presented. EULER intends to provide added value in comparison to the past projects by providing a harmonised, classified and prioritised collection of requirements from past projects, which includes: • SaBeCom analysis • Wintsec analysis • Safecom analysis • MESA analysis • Chorist analysis. The scenario presented is that of a Tsunami describing first hours operations capabilities, communication flows priority, organisation network composition and communication link requirements.

Requirements or needs identified in report	• Interaction between users
	  ▪ Real-time exchange of information between several authorized emergency personal
	• Applications and services
	  ▪ Data to be transported
	  ▪ Network congestion management requirement
	• Interoperability, adaptability and flexibility
	• Reliability and information assurance
	• Robustness
	• Sustainability
	• Environmental safety
	• Security
	  ▪ Authentication
	  ▪ Access control
	  ▪ Confidentiality
	  ▪ Integrity
	  ▪ Availability.

Possible applications identified in report	• Speech – speech quality, point to point duplex communications, direct mode, ambient listening

- Short messages – paging services, status monitoring, location services
  - able to identify the requested authorized emergency agent(s), and then deploy the appropriate technology to contact them
  - Status monitoring may include breathing air tank levels, accountability monitoring, distress buttons and vital signs monitoring.
  - Location services provide real-time information regarding the position of personnel or vehicles to a command point. The network must support three-dimensional geo-location information transmission.
- Access to databases
  - Variety of data applications including email (text messages), imaging, digital mapping / geographical information services, location services, video (real-time), video (slow-scan), remote database access, database replication, personnel monitoring
- File transfers
  - Supports bulk file transfer
- Images
  - Support images and scene photo transfers
- Video
  - Incident area network video communication service supporting full-duplex, peer-to-peer, mission-critical video and allow for late entry.
  - Near real-time video streaming.
- Multimedia conferencing
  - Incident area network highly interactive service transaction data
  - The network must support a signalling protocol that is capable of providing session control for both voice and video applications, as well as instant messaging
- Web
  - The network must support World Wide Web browser-based applications
- Email
  - Especially useful in noisy environments, or for difficult-to understand data, such as a license plate or a passport number
- Telemetry
  - Environmental telemetry e.g. waters flow and quality, providing instant information and a timely warning of severe change in conditions and early warnings.
  - Transmission of user and patient monitoring telemetry e.g. from inside the ambulance to the receiving hospital's emergency room
  - Transmission of geographical location data (Galileo) e.g. useful for tracking the location of field officers
  - Network of sensors, which are embedded into the field officer's terminals, such as temperature or dangerous gas sensors.
- Instant messaging - peer-to-peer
- Paging including voice paging to one or more participants
- Quality of service
- Pre-emption

	▪ Within all speech services there may exist a requirement for prioritisation and pre-emption of calls. ▪ This service shall allow an authorized user to intervene in an ongoing authority-to-authority call. • Priorities • Two-way communications • Multi-point to multi-point communications ▪ Belonging to groups ▪ Dynamic group creation/ deletion/ modification ▪ Dynamic Group Number Assignment ▪ Group members ▪ Talk group ▪ Group communication interoperability ▪ Group contain • Dynamic updating of data fields ▪ support two-way operation to accommodate the implementation of "smart" systems that automatically update data fields being transmitted from authorized and authenticated user devices
Possible benefits identified in report	Future public safety communications will benefit from the use of massive data transmissions to improve the efficiency of disaster recovery operations. An efficient radio spectrum management optimises the spectrum sharing between the different public safety organizations according to their respective and evolving needs. Sophisticated spectrum management algorithms, which can adapt to changes in the radio environment, can help using radio spectrum more efficiently. EULER proposes a system in which each subset is able to dynamically change the operating frequency band and bandwidth, is able to reallocate its use of radio spectrum bands, is aware of the existence of other wireless communications systems transmitting in the incident area, has sensing capabilities, and is able to inform the other subsets of its spectrum usage in its coverage. All of this contributes to provide a wireless system that is more reliable and resistant to interferences.
Can the benefits be realised using commercial networks	Not applicable
Possible scenarios identified	First Hours of International, state and local Public Safety Operations in response to a Tsunami. • Tsunami monitoring systems are positioned at strategic locations. • First hours: until local and mobile command centres are activated and connected to country's Emergency Operations Centres (EOC), which can last some days due to inundation and receding water. • Ground based wire and fibre communications to the outside world are temporarily disrupted. • First link establishment of V-UHF radio communications (air-to-ship, air-to-ground, air-to-air, ground-to-ground (voice, video, data)). • Information flow – search and rescue first operators, situation awareness video supported.
Any other relevant information from the report	Not applicable

C.14 TETRA Association Spectrum Group study

Item	*Description*
Document title	What data services will the future bring – from a TETRA perspective
Author	TETRA Association Spectrum Group
Version	Indicated as "draft" (November 2009)
Abstract	The document discusses the killer application for TETRA being mission critical group calls, and then discusses the feasibility of carrying missing critical group calls, and other public safety data applications, over LTE networks. The conclusion is that LTE is unlikely to be feasible to replace private networks in the short term, because (i) the LTE standard would need to be modified to support true multicasting group call capability (currently group calls via LTE are proposed to be delivered through a set of unicast IP streams, which means each member of the call receives his/her own copy of the voice stream. This can lead to quality problems (due to echo) and capacity issues due to the cell load created through transmission of multiple copies of the same IP stream), and (ii) LTE would also need to be modified to support direct mode (i.e. terminal to terminal calls that do not go via the LTE network) (iii) Emergency Services require a range of terminals (rugged, environmentally sensitive, covert) which commercial vendors do not provide, and so this would require special development (refers to the case where the GSM standard was modified for the railways, however the modifications required to GSM to create GSM-R were sufficiently large that whilst GSM is supported by many vendors, GSM-R is limited to very few, and prices for GSM-R are even higher than for TETRA).
Requirements or needs identified in report	1. Group calls where all users on the call, without substantial network overheads and/or cell capacity issues, receive the same transmission simultaneously. 2. Nationwide coverage, including 'difficult' geographies and indoors 3. Layered priorities/pre-emption (i.e. enabling emergency services to have priority access over commercial traffic, and enabling higher ranks of officer pre-emptive access over lower-ranked officers where required) 4. Queued calls, and the ability to configure queuing conditions 5. User prioritisation (e.g. calls cant go ahead until nominated callers join the call) 6. Encryption of different levels (over the air and end to end)
Possible applications identified in report	Mainly refers to existing functionality e.g.: • Direct mode – radio to radio communications outside the infrastructure • Individual calls using half duplex PTT (push to talk) mode • Status messages, which are used as fast efficient messages in addition to the more standard Short Data/Short Message text services • Multiple levels of encryption, both end to end and air interface. • Dynamic group management – providing groups over the air, temporarily or permanently • Broadcast calls, both with static and dynamic user base • Group scanning with talkback functions • Paging from one service into another, and simultaneous services Also refers to the need for dispatcher terminals
Possible benefits identified	Bespoke, privately run networks for the emergency services can be developed to give the required level of terminal ruggedness, environmental

in report	protection, audio levels, battery life, accessories, and resilience, coverage, availability and security at the network level. These factors make it difficult to reuse networks and terminals taken from the consumer market and to obtain the economies of scale that the consumer market brings.
Can the benefits be realised using commercial networks	Primary reason given is that there is currently no standardisation activity going on at present to adapt LTE to meet emergency services requirements, and if there was to be activity, this would take some time to complete. Also refers to the additional cost to modify commercial networks to deliver emergency services functionality [which *assumes* this cost is higher than the cost to deploy a new, bespoke private network for the emergency services]. Reasons listed in the document: 1. A public network provider will want to invest in coverage where the population, and so where the revenue generation is, with little incentive to invest in areas of low-density population. The cost of network expansion may have to be borne by the public safety community alone. 2. The public safety community will – through a tender process – have to select one of the providers, and fund the expansion of that system to provide the required degree of coverage. That in turn will distort competition and may be the basis for litigation. 3. Bespoke mission critical networks are usually designed with higher degrees of resilience, including multiple levels of fallback with emergency power supplies, alternate link routing and local call switching even within a single base station. These facilities are not provided to the same degree on a public network. 4. In conditions of local or national emergency, public networks typically become overloaded as their normal customer base naturally wants to communicate at the same time. It can be difficult to guarantee the public safety community access in these conditions. 5. In high threat conditions, e.g. terrorist threats or in times of war, public networks can be deliberately switched off to prevent terrorist communications for coordination or for remote activation of attacks.
Possible scenarios identified	Not applicable
Any other relevant information from the report	Refers to WiMAX being "easier to deploy for a privately owned mission critical user base", due to network scalability (more flexible bandwidth choices and no need for harmonised paired bands) and less spectrum being needed (i.e. because it uses unpaired spectrum).

C.15 Wireless broadband study by Public Safety Spectrum Trust Chairman

Item	*Description*
Document title	Public Safety Radio Communications; Wireless Broadband is not an alternative to LMR mission critical voice systems
Author	Chief Harlin R. McEwen Chairman, Communications & Technology Committee International Association of Chiefs of Police
Version	Draft (12 October 2009)
Abstract	The paper discusses using wireless broadband for data sharing purposes and the danger of assuming that wireless broadband will offer an alternative to traditional LMR (land mobile radio) mission critical public safety voice systems.
Requirements or needs identified in report	Before LMR systems could be supplanted, broadband services would first need to be deployed to the level that provides the same extensive coverage that mission critical voice systems provide, including in-building coverage in many instances. Because coverage area decreases as data rate increases, covering the same area at the same level of reliability with broadband services will require even more sites than the number used today for voice. If LTE developers were to eventually develop standards for mission critical broadband voice, the public safety community would need to be involved in the equipment development and would need to see it tested and work in the actual public safety environment on a trial basis before they would be convinced it would be reliable enough to use as an alternative to current LMR narrowband voice systems. System operators and users then would need time to procure and deploy appropriate equipment and devices. The reality of broadband coverage build-out, standards and equipment development, testing in the public safety environment, and follow-on procurement means it would likely be 10 to 15 years or more before most public safety entities would be in a position to seriously consider substituting broadband voice for today's LMR mission critical voice solutions. The goal is that a Shared Wireless Broadband Network would give public safety: • Broadband data services (such as text messaging, photos, diagrams, and streaming video) not currently available in most existing public safety land mobile systems • A hardened public safety network with infrastructure built to withstand local natural hazards (tornadoes, hurricanes, earthquakes, floods, etc) that would include strengthened towers and backup power with fuel supplies to withstand long term outages of public power sources • Nationwide roaming and interoperability for local, state, and federal public safety agencies (police, fire and EMS) and other emergency services such as transportation, health care, and utilities • Access to the Public Switched Telephone Network (PSTN) similar to current commercial cellular services • Push-to-talk, one to one and one to many radio capability that would provide a back-up to (but not replace) traditional public safety land mobile mission critical voice systems • Access to satellite services to provide reliable nationwide communications where terrestrial services either do not exist or are temporarily out of service

Possible applications identified in report	Not applicable
Possible benefits identified in report	Not applicable
Can the benefits be realised using commercial networks	The fact is there are currently no standards being developed or even planned to provide such a service. The public safety community has endorsed Long Term Evolution (LTE) as the preferred broadband standard for public safety data products and the latest version of that standard (V8) is strictly a data standard that does not include voice capability. The next version (V9) due in late 2010 or early 2011 is planned to include VoIP capabilities but that version will not have any capability to provide one-to-many communications and talk around (unit to unit) voice necessary for mission critical public safety communications. LTE is a commercial standard that does not recognize the mission critical voice communications needs of public safety. That means that if a first responder cannot reach the network (i.e. a police officer in trouble in a building and his radio unit cannot reach a repeater) or there is no network then the unit is useless. That means no communications and a possible life-threatening outcome for the police officer.
Possible scenarios identified	Not applicable
Any other relevant information from the report	On September 11, 1996, PSWAC released a report setting forth the current and future spectrum needs of public safety. Among the findings of the PSWAC report was that 97.5 MHz of new public safety spectrum was needed by 2010, including 25 MHz within five years (i.e., by 2001). In November 2007, the FCC issued the Public Safety Spectrum Trust (PSST) a nationwide Public Safety Broadband License (PSBL) for 12 MHz of spectrum in the upper 700 MHz band (10 MHz of broadband spectrum and 2 MHz of guard band spectrum). The FCC Second Report and Order also directed that the Public Safety Broadband Licensee would negotiate with the commercial operator(s) to set appropriate rules and technical standards to ensure maximum interoperability, reliability, redundancy, competition, innovation and choices for public safety customers using this spectrum. The network would include a satellite-based element to ensure continuous operations when terrestrial/ground-based equipment is knocked out or in areas where there is no terrestrial service. From January 24, 2008 through March 18, 2008, the FCC conducted Auction 73. Almost all of the 700 MHz spectrum, with the exception of the D Block, was sold with the proceeds reaching almost $20 billion. Although there has been a lot of speculation as to why the D Block was not sold, most in public safety believe it was because the industry had its eye on the unencumbered spectrum that did not include any public safety requirements. On March 20, 2008, the FCC issued an order delaying further D Block action until further notice. One issue raised in the Hearing by some Members of Congress were concerns about how much it will cost to build a nationwide public safety broadband network and how it will be funded. Estimates of $10 billion to $40 billion have been floated without any real supporting documentation. There is general agreement that if public safety and the private sector can leverage existing private and public infrastructure the cost can be significantly reduced. One commercial company has said that if existing commercial infrastructure was used their cost estimate would be about $13 billion. Eventual total cost of the network will also be influenced by local build-out decisions. Some commercial companies who have indicated their interest and support for a nationwide public/private network have said it is feasible to fund a nationwide public/private network through the public/private partnerships envisioned. This appears to be the only current option unless Congress were to fund the build out.

C.16 Hansard Report

Item	Description
Document title	Lords Hansard text (debate on the second reading of the Digital Economy Bill) – document reference XEMS1002 – Lords Hansard text
Author	www.parliament.uk (transcript of debate)
Publication date	2 December 2009
Abstract	During the second reading of the Digital Economy Bill, Lord Lucas raised a proposed amendment relating to reserving spectrum for the Emergency Services, suggesting that 15 MHz of spectrum within the band 'allocated by the EU' (referring to spectrum below 1 GHz, and digital dividend spectrum specifically, which is discussed in Council recommendation 10141/09). The amendment asks Ofcom to consider reserving spectrum for Emergency Services use.
Requirements or needs identified in report	"We will want our emergency services to have a really modern and effective system that is equivalent to the iPhone".
Possible applications identified in report	Not applicable
Possible benefits identified in report	1. Many of the companies who produce TETRA equipment are based in the UK and therefore the UK export market has benefited from the harmonised development of the TETRA standard 2. Vital for national security reasons
Can the benefits be realised using commercial networks	Not applicable
Possible scenarios identified	Not applicable
Any other relevant information from the report	Not applicable

C.17 Safecom document

Item	Description
Document title	Department of Homeland Security, Public Safety Statement of Requirements for Communications and Interoperability (including annex on SAFECOM summit)
Author	US Department of Homeland Security Office for Interoperability and Compatibility (OIC)
Publication date	Volume II Version 1.2 (August 2008)
Abstract	Document contains the assembled requirements for system of interoperable public safety communications across all local and national 'first responder' emergency services communications systems. Describes the public safety environment and the types of applications that might be expected to be used in the future. Two volumes exist – volume 1 is a qualitative description of the types of application that might be required, and volume is quantitative (i.e. in terms of specific network performance requirements and metrics).
Requirements or needs identified in report	Requirements include: • Different hierarchies of users and system • Different modes of communication (with/without a network) • The need for security in communications and in information • Support for command and control processes (i.e. mobilisation of teams, prioritisation of communication, decision making) • Describes a 'system of systems' incorporating all public safety communications modal requirements from wide area networks through to local networks, incident-specific networks and personal area networks (e.g. representing the set of devices that an individual public safety officer users) • Ground based and aerial pictures taken at the scene of an incident, to inform follow on action (e.g. alert hospitals to numbers and types of casualty) • Telemedicine techniques require high quality video images to enable viewing of things like patient's burns or skin/bone details • Emergency button for high-priority treatment of emergency calls • Need to establish connection with a large number of users • Ability to restrict access to information to selected individuals.
Possible applications identified in report	Includes a detailed list of different voice, messaging, data, image and video applications for each of police, fire and ambulance services, including who the communication occurs with, for what purpose and with what special constraints. Examples: • Personal area networks e.g. if a bullet-proof vest detects an impact or a fire-fighters helmet is impacted, it can originate a message to the appropriate person • Full duplex, peer to peer and mission critical voice applications • Peer to peer instant messaging • Automated database updating • Bulk file downloads/uploads • Email/Internet

	• Biometric identification techniques • Voice language translation.
Possible benefits identified in report	Diagnosis and treatment in routine health cases for remote/rural communities e.g. remote doctor's viewing of a patient.
Can the benefits be realised using commercial networks	Special constraints include: • High priority calls that need to be secured to protect privacy and maintain chain-of-command authority • Very high resolution video pictures • High priority images requiring rapid transportation between different officers • Voice communications needed to authenticate and authorise personnel to follow specific courses of action • Requirement to be able to communicate when local infrastructure may not be operational (e.g. due to a major incident).
Possible scenarios identified	Describes a number of details scenarios in pages 14-18 of the document: • EMS – routine patient services and car crash scenario • Fire – residential fire scenario • Law enforcement – traffic stop scenario • Multi service – explosion, hurricane, earthquake.
Any other relevant information from the report	The document includes a detailed statement of functional requirements for device/terminal features for police, fire and ambulance users, e.g. interfaces, storage requirements - some of which are typically not supported in commercial terminals, which supports the argument about the requirement for dedicated networks (and associated terminals).

C.18 Westminster e-Forum

Item	*Description*
Document title	Westminster eForum keynote seminar, Emergency Services and Public Safety Spectrum
Author	Westminster eForum (transcript of event)
Publication date	11 June 2009
Abstract	The document describes proceedings at the Westminster eForum keynote seminar on public safety spectrum held during June 2009.
Requirements or needs identified in report	Discusses the different functional requirements that the Emergency Services have: • Complete resilience • Pre-emption functionality • Coverage • Confidentiality • Confidence (that a connection can be made immediately) • Operation in remote and extreme conditions.
Possible applications identified in report	Possible need for a portfolio of technologies including sensing devices etc. Requirements for "all functionality in one device" Emergency button functionality important Talk groups/dispatch More data/faster data Transfer of images and pictures.
Possible benefits identified in report	Not applicable
Can the benefits be realised using commercial networks	Commercial networks not designed for resilient communications (comment from Ericsson: can resilience not be provided through emergency services having access to all five mobile networks, rather than just the one? Also, pre-emption functionality is built into 3GPP standards, it is just not fully implemented at present).
Possible scenarios identified	Not applicable
Any other relevant information from the report	Discussion about different spectrum alternatives and digital dividend spectrum. Martin Cave gave presentation on evaluating alternatives – suggesting there is a "substitution margin" between using dedicated networks and using general (commercial) networks, that should be evaluated.

C.19 PSC Europe White Paper

Item	Description
Document title	Public Safety First
Author	Jeppe Jepsen
Version	-
Abstract	This white paper discusses the need for spectrum for Public Safety Services (PSS), through the reallocation of Digital Dividend spectrum, putting forward arguments for further dedicated spectrum for mission critical communications and provides a view of the technical and usage characteristics of next generation PSS radio systems.
Requirements or needs identified in report	Need to be able to gain access to a wireless service to increase efficiency, make it easier to share information, reduce costs, while on the move, and using networks, which are secure, reliable, resilient and available across a wide geographic area regardless of population density. The need for ubiquitous coverage and spectrum between current PSS allocations (around 380MHz and 862MHz) is essential. PSS mission critical broadband communications will empower PSS organizations to move human resources into field, increasing situational awareness and facilitating command and control. Broadband communications will be used to collect and disseminate timely information such as medical records, details of dangerous substances, maps, pictures and video to the various emergency responders. Broadband communications can, for example, support Most mission critical operations depend on voice communications and currently have only two 5 MHz-wide blocks available in the harmonised spectrum. There are already problems with supporting voice traffic at major incidents and planned events. The integrated broadband data services, which are emerging for PSS organizations, require more bandwidth - ideally two paired 15 MHz-wide blocks – 15 MHz, for day to-day use and additional 15 for major incidents. PSS organisations require this dedicated spectrum and their own networks because of the flexibility it affords – the ability to meet their own specific requirements so that they can maximise the advantages provided by broadband services. Dedicated networks employing a dedicated spectrum band are widely used today because it is considered the best way to provide secure, robust and immediate communications for PSS radio systems. The spectrum released can provide access to spectrum in the amounts and within the timescales needed by PSS organizations. PSS organisations require their own spectrum to deploy whatever technologies can meet their service and application needs in an appropriately designed network to meet their operational requirements. Also important when identifying spectrum to take into account other considerations including a sufficient size market for the development of equipment by vendors and the cost of ownership of networks required to support the services and the match against future budgets such as economies of scale and potential for inter-operability.
Possible applications identified in report	These include: • remote checking of information such as passport and biometric details • the sending of detailed photographic images of children lost or people

	wanted to officers out in the field so they can act on requests immediately • providing access to the Fire services Gazetteer – a document containing information on what hazardous materials might be kept on a premises • transmission of live video information to the central command and control personnel so they can have access to the same visual information as their personnel in the field • relaying of ad-hoc video and surveillance camera real time information to patrol cars responding to incidents; or • sending of full data on a patient's condition from the ambulance to the hospital.
Possible benefits identified in report	Societal welfare – to protect life, welfare, and property.
Can the benefits be realised using commercial networks	Possibly some services offered by commercial networks are suitable for certain public safety applications. However, because the mission for PSS organisations necessitates specific requirements for robust mission critical communications in terms of access, redundancy and quality of service, these demands are not suited for commercial networks.
Possible scenarios identified	Not applicable
Any other relevant information from the report	There is a significant risk that basing the award of spectrum on price or average utilization will fail to provide PSS users with sufficient spectral resources. The utilization rate of public spectrum ranges from near constant (e.g. some radar systems and fixed point to point radio links), to mostly idle (e.g. some emergency communications spectrum). A dedicated network in a dedicated spectrum band allocated and assigned to PSS users is the best way to ensure secure, robust and immediate radio communications.

C.20 Report for BAPCO

Item	*Description*
Document title	The "Business Case" for Blue Light Spectrum
Author	David Happy
Publication date	26 August 2009
Abstract	This document was written for BAPCO to justify the request for dedicated and harmonised spectrum for blue light services. It discusses the operational need, current policy, why the current system is not working and why it is not possible to quantify a human life.
Requirements or needs identified in report	Changes in operational needs due to: • Terrorist threats (9/11, July bombings etc.) • Natural disasters (flooding in the UK) • Technical advances of mobile technology • Future events e.g. London 2012 Olympics In a serious accident, the ability for services to inter work seamlessly would improve coordination and lead to markedly improved service levels.
Possible applications identified in report	The ability of a police or fire operative to be able to transmit in real-time images of casualties to local Hospital professionals could assist in preparing the Casualty departments with information and knowledge that would otherwise not be available until the triage process started on arrival at Casualty. Missing person tracing and the ability to use technology to "fit" real-time images of suspects with data already held on them is another way in which the UK could "work smarter."
Possible benefits identified in report	Safety of life.
Can the benefits be realised using commercial networks	Possibly but there is not enough spectrum for the network to work properly.
Possible scenarios identified	Not applicable
Any other relevant information from the report	In the USA, there is a nation-wide reservation of 97MHz of spectrum following on from a review of spectrum shortage. During 9/11 there were communication problems that could have been prevented and which led to many avoidable deaths amongst fire fighters. During June 2009, The European Council adopted a Recommendation (recommendation 10141/09) setting out the importance of cross border cooperation between police forces. This follows the so-called "Pruem decision" on the stepping up of cross border cooperation, particularly in combating terrorism and cross-border crime. It is widely recognised that in an increasingly interconnected world, more crime will be of a cross border nature – and that this trend will increase. The Council make several critical recommendations as regards next generation spectrum for the use of the blue light services, including (page 4): "the Electronic Communication Committee (CEPT/ECC) be tasked to study the possibility of obtaining sufficient additional frequency allocation below 1GHz for the development of future law-enforcement and public-safety voice and high speed data networks." And: "that ministries responsible for police and justice be encouraged to contact their counterparts responsible for spectrum policy to ask for their assistance

with the above proposal, given the important role of the national frequency administrations."

The Cave Audit of 2005 at section 8.5 already makes reference to emergency spectrum, and makes clear that the Cabinet Office is responsible where there is an emergency. We have a pandemic now, swine flu, and therefore the circumstances already exist for this provision to be invoked should the blue light services so request.

Abstract

In response to a request for technical advice by Public Safety Canada on behalf of national public safety stakeholders, the Centre for Security Science conducted a technical assessment of the 700 MHz spectrum requirements for broadband mobile data communications for public safety and security. The impetus to this assessment relates to the Industry Canada call for consultation SMSE-018-10. The goal was to determine how much spectrum is required to meet the needs of the public safety community for mobile broadband wireless data communications within a 20-year time frame. The data demand for recurring emergency situations was modeled through an interactive process with active participation from Canadian public safety stakeholders. In addition, the capabilities of LTE technology to support the data demands were also modeled. The results show that the amount of bandwidth required to satisfy the needs of public safety is greater than 20MHz in the near-to-mid term, and likely to also exceed 20MHz in the long term, despite advances in technology. This result is based on an analysis that applies relatively conservative estimates for the growth in demand for mobile data communications for public safety and security applications, and relatively aggressive estimates for the rate of technological improvement of spectrum efficiency projected into the future.

Résumé

En réponse à une demande de conseils techniques faite par Sécurité publique Canada au nom des intervenants nationaux de la sécurité publique, le Centre des sciences pour la sécurité a effectué une évaluation technique des besoins de la fréquence de 700 MHz pour la transmission mobile à large bande de données destinée à la sécurité publique. C’est l’appel de consultation SMSE-018-10 d’Industrie Canada qui a motivé l’exécution de cette évaluation. L’objectif consistait à déterminer quelle part du spectre est requise pour répondre aux besoins du milieu de la sécurité publique pour la transmission mobile de données à large bande au cours des 20 prochaines années. La demande en données pour les situations d’urgences récurrentes a été modélisée à l’aide d’un processus interactif auquel les intervenants de la sécurité publique du Canada ont participé activement. Il y a de plus une modélisation des capacités de la technologie LTE pour répondre aux demandes de données. Les résultats démontrent que la part de la bande passante nécessaire pour répondre aux besoins de la sécurité publique est supérieure à 20 MHz à court et à moyen terme, et dépassera aussi probablement 20 MHz à long terme, et ce, malgré les progrès technologiques. Ce résultat repose sur une analyse ayant recours à des évaluations relativement prudentes de la croissance de la demande pour la transmission mobile de données à des fins de sécurité publique, ainsi qu’à des évaluations relativement ambitieuses du degré d’amélioration technologique de l’efficacité spectrale dans le futur.

Executive summary

700MHz spectrum requirements for Canadian public safety interoperable mobile broadband data communications.

Claudio Lucente, MARTELLO DEFENSE SECURITY CONSULTANTS INC.

DRDC CSS CR 2011-01

In response to a request for technical advice by Public Safety Canada and on behalf of the national public safety community, the Centre for Security Science, with technical oversight by the Communications Research Center, conducted a scientific assessment of the 700 MHz spectrum requirements for broadband mobile data communications. This assessment is provided in support of the Industry Canada call for consultation SMSE-018-10.

The conversion of the broadcast television from analog to digital signals and the resulting re-allocation of the channels has attracted significant interest for the vacated RF spectrum on the part of commercial, private, and public entities. In particular, the Canadian public safety community has a strong interest in a segment of the 700MHz spectrum as described in the Industry Canada call for consultation (SMSE-018-10). Given the excellent propagation properties of this frequency band, it views this as a unique opportunity to lay the foundation for a national mobile broadband communications network that will allow various public safety agencies to better plan, coordinate, and execute their missions, for their day-to-day operations and when responding to crisis events.

New technologies and applications are at hand that can enhance situational awareness and improve coordination between public safety personnel. The mobile broadband wireless network must have suitable bandwidth to provide the data throughput required by the many applications required by today's public safety personnel such as real-time video surveillance, vehicle and blue force tracking devices, ambulance patient video. The bandwidth requirements will evidently vary depending on the operations being conducted be it day-to-day routine calls, crowd control, or major emergency situations. Since the network must be designed to provide connectivity that responders can rely on at all time, the bandwidth requirements must be addressed in the context of how responders intend to use the mobile broadband network during emergencies.

In order to assess the requirement with appropriate context and relevance, stakeholders were consulted across the nation, facilitated through linkages provided by the Canadian Interoperable Technologies Interest Group. Three incident scenarios were selected as case studies for public safety stakeholders to develop the incident-response profiles. The profiles consisted of establishing how many resources and assets would be assigned to each incident and, what applications would they make use of during each incident. The incidents that were chosen as case studies represent major but commonly re-occurring events (such as a sports event). We know that catastrophic events of the scale of a major earthquake or a concerted terrorist attack (9/11) would create demands that would far exceed any available spectrum and so such situations were not considered in the analysis.

The data throughput for each application was derived from empirical studies conducted by public safety agencies, support organizations, and research labs. Thus, the Data Demand Model (DDM) is derived from the incident-response profiles and the applications throughput requirements, in addition to growth assumptions over a 20-year horizon. Particular attention was paid to tactical video as it is expected to prevail in enhancing situational awareness and is often critical, particularly to security operations. It is also the largest consumer of bandwidth. As such, various techniques are considered in the DDM to reduce the preserve bandwidth requirement in the presence of video traffic.

Because of the large push by the commercial sector to deploy Long Term evolution (LTE) networks as the 4th generation of cellular system and since the United States has selected LTE as the technology for public safety mobile broadband, using the same technology in Canada would leverage the economies of scale and enhance interoperability between Canadian and US public safety agencies LTE was therefore selected as the basis to develop the Capacity Model for this report. There are substantial research efforts underway to enhance the capacity of LTE and therefore, the Capacity Model introduces a factor to account for a number of anticipated enhancements in spectral efficiency at various intervals over the 20-year horizon of the model.

Finally, the required bandwidth is revealed by correlating the data demand with the capacity. Several fundamental assumptions are used in the models such as the rate at which research into spectral efficiency is transformed into reality and, the number of users accessing the same applications simultaneously. The effect of varying these assumptions on required bandwidth is examined, as is the effect of uncertainty in predictions, which increases with time particularly as we look into the future 15-20 years.

The result of the modeling, taking into account uncertainty factors, shows that the amount of bandwidth required to satisfy the needs of public safety to conduct their missions during commonly re-occurring major emergency situations with modern tools and applications is greater than 20MHz in the near-to-mid term, and likely to also exceed 20MHz in the long term, despite advances in technology. Clearly even with the full 10 + 10 MHz allocated, the community will need to take measures to efficiently manage broadband data communications carefully during periods of peak demand.

Sommaire

Évaluation technique des besoins de la fréquence de 700 MHz réservée à la sécurité publique pour la transmission mobile à large bande de données

Claudio Lucente, MARTELLO DEFENSE SECURITY CONSULTANTS INC.

DRDC CSS CR 2011-01

En réponse à une demande de conseils techniques faite par Sécurité publique Canada au nom de la collectivité nationale de la sécurité publique, le Centre des sciences pour la sécurité, sous la supervision technique du Centre de recherches sur les communications, a mené une évaluation scientifique des besoins de la fréquence de 700 MHz pour la transmission mobile de données à large bande. Cette évaluation vient en soutien à la demande de consultation SMSE-018-10 d'Industrie Canada.

La transition des signaux analogues aux signaux numériques des services de télédiffusion et la nouvelle répartition des canaux ont suscité un vif intérêt vis-à-vis du spectre des radiofréquences libéré chez les entités commerciales, privées et publiques. Le milieu canadien de la sécurité publique s'intéresse énormément à un segment de la bande de 700 MHz tel qu'il est décrit dans la demande de consultation SMSE-018-10 d'Industrie Canada. Étant donné les excellentes propriétés de propagation de cette bande de fréquence, on considère qu'il s'agit d'une occasion unique de jeter les bases d'un réseau national de transmission mobile à large bande qui permettra aux divers organismes de sécurité publique de mieux planifier, coordonner et exécuter leurs mandats, tant dans le cadre de leurs activités quotidiennes que lors des interventions en situation de crise.

Il existe de nouvelles technologies et applications qui peuvent accroître la connaissance de la situation et améliorer la coordination entre les intervenants de la sécurité publique. Le réseau mobile sans fil à large bande doit avoir une bande passante suffisante pour fournir le débit de données nécessaires aux nombreuses applications exigées de nos jours par les intervenants de la sécurité publique, comme la vidéosurveillance en temps réel, les appareils de suivi des véhicules et des forces bleus et la vidéo de patients transportés par ambulance. Les besoins en bande passante varieront évidemment en fonction des activités, qu'il s'agisse d'appels quotidiens de routine, du contrôle des foules ou de situations d'urgence majeures. Puisque le réseau doit être conçu de manière à offrir une connectivité à laquelle les intervenants peuvent se fier en tout temps, il faut tenir compte des besoins en bande passante en fonction de la manière dont les intervenants ont l'intention d'utiliser le réseau mobile à large bande pendant des situations d'urgence.

En vue d'évaluer les besoins en fonction des bons contextes et de leur pertinence, on a consulté des intervenants partout aux pays, grâce aux liens fournis par le Groupe d'intérêt canadien en technologie de l'interopérabilité. Trois scénarios d'incident ont servi d'études de cas aux intervenants de la sécurité publique pour définir les profils d'intervention des incidents. Les profils visaient à établir la quantité de ressources et de

biens qui seraient affectés à chaque incident et à déterminer quelles applications ils utiliseraient dans chaque cas. Les incidents choisis à titre d'études de cas représentent des événements majeurs récurrents (comme une manifestation sportive). Nous savons que les catastrophes comme un important tremblement de terre ou une attaque terroriste concertée (attaques du 11 septembre) engendreraient des demandes qui iraient bien au-delà de tout spectre disponible. Par conséquent, de telles situations n'ont pas été prises en considération dans l'analyse.

Le débit des données pour chaque application a été obtenu à partir d'études empiriques effectuées par des organismes de sécurité publique, des organismes de soutien et des laboratoires de recherche. Par conséquent, le modèle de demande de données repose sur les profils d'intervention aux incidents et les besoins des applications en débit des données, ainsi que sur les hypothèses de croissance pour les 20 prochaines années. On a porté une attention particulière à la vidéo à des fins tactiques puisque celle-ci devrait s'imposer pour améliorer la connaissance de la situation et s'avère souvent essentielle, notamment aux activités de sécurité. C'est aussi elle qui utilise le plus de bande passante. Le modèle de demande de données a donc pris en considération diverses technologies pour réduire le besoin de bande passante réservée en présence de trafic vidéo.

En raison de l'offensive du secteur commercial visant la mise en place de réseaux LTE en guise de 4^{e} génération de système cellulaire et puisque les États-Unis ont choisi la technologie LTE pour la transmission mobile à large bande de la sécurité publique, l'utilisation de la même technologie au Canada permettrait de faire des économies d'échelle et améliorerait l'interopérabilité entre les organismes de sécurité publique des États-Unis et du Canada. La technologie LTE a donc servi de base à l'élaboration du modèle de capacité du présent rapport. D'importants travaux de recherche sont en cours en vue d'améliorer la capacité de la technologie LTE. Par conséquent, le modèle de capacité introduit un facteur qui tient compte de certaines améliorations prévues de l'efficacité spectrale à divers intervalles au cours des 20 prochaines années du modèle.

Enfin, la bande passante nécessaire est déterminée par la corrélation entre la demande de données et la capacité. Les modèles utilisent plusieurs hypothèses de base, comme la vitesse à laquelle la recherche sur l'efficacité spectrale se transforme en application pratique et le nombre d'utilisateurs accédant simultanément aux mêmes applications. On examine les répercussions d'une variation de ces hypothèses sur la bande passante ainsi que l'incidence de l'incertitude dans les prédictions, qui augmente au fil du temps puisqu'il s'agit d'une évaluation portant sur les 15 à 20 prochaines années.

Les résultats de la modélisation, qui tient compte des facteurs d'incertitude, démontrent que la part de la bande passante nécessaire aux activités du milieu de la sécurité publique ayant recours aux outils et aux applications modernes lors de situations d'urgence majeures et récurrentes est supérieure à 20 MHz à court et à moyen terme, et qu'elle dépassera probablement 20 MHz à long terme, et ce, malgré les progrès technologiques. De toute évidence, même avec une pleine attribution de 10 + 10 MHz, la communauté devra prendre des mesures pour gérer efficacement et prudemment la transmission de données à large bande pendant les périodes de demande de pointe.

This work was supported by Defence Research and Development Canada Centre for Security Science through the Public Security Technical Program (PSTP) subproject EMSI-02-302 (Contract # U6800-117762/001/SQ Addendum #1). We would like to thank the federal scientists of the Communications Research Centre for their technical support and oversight of the project. We also wish to acknowledge the cooperative sharing of information from various Canadian first responder agencies, facilitated through links provided through the Canadian Interoperability Technology Interest Group.

1 Introduction

The demise of analogue broadcast television and the resulting re-allocation of broadcast television channels has attracted significant interest for the vacated RF spectrum on the part of commercial, private, and public entities. In particular, the Canadian public safety community has expressed a strong interest in a segment of the 700MHz spectrum. It views this moment in time as a unique opportunity to lay the foundation for a national mobile broadband communications network that will allow various public safety agencies to better plan, coordinate, and execute their missions, whether it is for their day-to-day operations or when responding to crisis events.

Such a network could enable interoperable broadband communications among Canadian public safety entities and with international agencies during joint operations, such as with the US Department of Homeland Security, provided that technology and spectrum are aligned between Canada and the US. It would enable the goals of Canada's National Strategy for Communications Interoperability[*] .

The demands placed on a mobile broadband data communications network by the public safety community depends strongly on the nature of the missions it executes and the applications it uses during those missions. Situational Awareness (SA) and the ability to coordinate broadly and effectively in improvised circumstances are fundamental capabilities in order to execute a mission in the safest and most expedient manner possible. Whereas, currently, voice communications via Land Mobile Radio (LMR) is the most commonly used method to coordinate and establish SA, it is expected that tactical video, will play an increasingly important role to enhance SA, while LMR will remain the key voice communications tool for the foreseeable future.

Mobile broadband data services will give rise to new applications and innovative uses for data communications by the public safety community. It is envisaged that access to a mobile broadband network will extend to a user-group that is peripheral to first responders and those that occupy supporting roles. As such, the data demands will be driven by the use of new tools, new users, and new applications which, in turn, will foster greater reliance by first responders on the tools and supporting community in the response to incidents.

The goal of this study is to determine how much spectrum is required to meet the needs of the Canadian public safety community for mobile broadband wireless data communications within a 20-year time frame. The results of this study and its conclusions are derived from the correlation of the community's data demands and the capacity of 4th Generation wireless technology to support the applications that first responders intend to use. Fundamental assumptions are validated and inputs are obtained via an interactive process with active participation from public safety stakeholders and federal government researchers. The methods, assumptions, and results are benchmarked against similar studies that have been performed in the USA. [1, 3, 21]

1.1 The 700MHz band

The channelization of the Canadian 700MHz band is under study by Industry Canada and so the US 700MHz spectrum allocation is shown here for reference. Figure 1.1 illustrates the US channelization plan for the 700MHz spectrum. Note that Band-14 (circled) spans 10MHz in the down-link (758MHz – 768MHz) and 10MHz in the up-link (788MHz – 798MHz). If the FCC and US Congress allocate the D Block to public safety then that would represent 2x10MHz of spectrum. In this report references to 10MHz LTE pertain to either the up-link or down-link channel bandwidth. When referring to both the up-link and down-link channel bandwidths then it is stated as 10+10MHz or 20MHz.

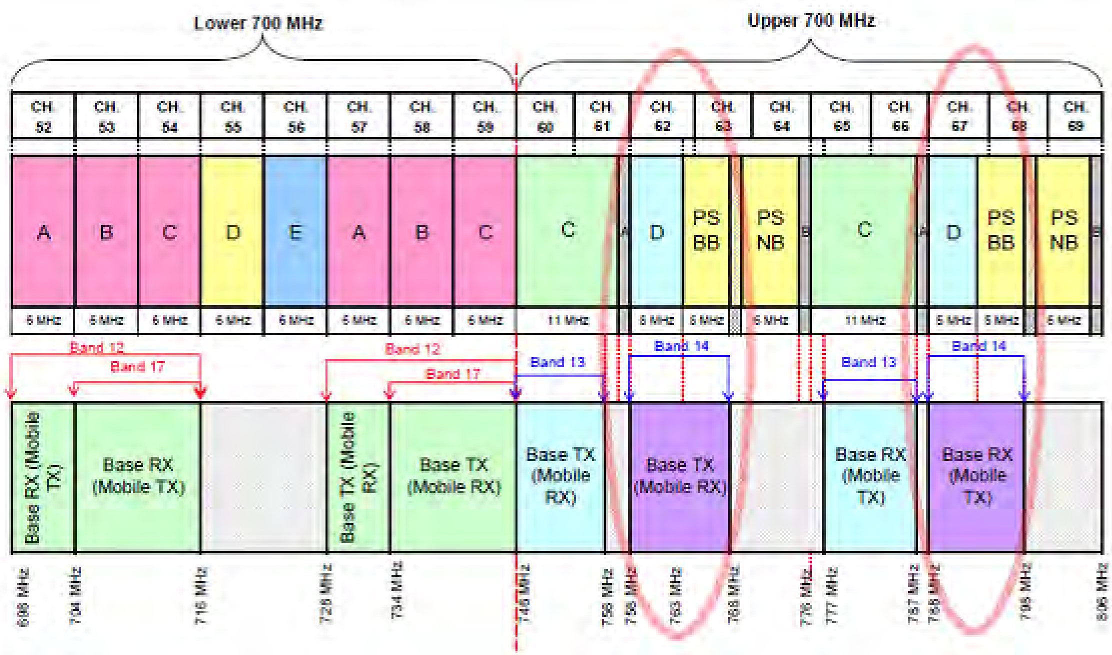

Figure 1.1: US channelization plan for 700MHz spectrum

2 Methodology

The bandwidth required to support public safety operations is based on a number of factors, of which the two most important ones are:

a) Usage in terms of data demand

The data demand, expressed in bits per second, is defined by the sum of the Up-link and Down-link data rates required to sustain the various applications needed to support public safety's data communications needs in day-to-day operations and when responding to emergency situations.

b) Network infrastructure

The amount of bandwidth required to carry the data demand is based on the network infrastructure selected, the communications protocol, and the network architecture.

In this Chapter, the methodology used to define both the data usage and the bandwidth, based on the infrastructure is discussed. The data demand is derived and quantified in §3.

2.1 Usage

The process to establish the data demand is illustrated in Figure 2.1. It involves public safety stakeholders to define how they would use a mobile broadband network and what applications they would make use of. The demand is evaluated for day-to-day operations and for three incident scenario case studies, which represent recurring emergency situations typically encountered by public safety agencies. The case studies are described in §3.1. The Model includes a demand growth factor to account for applications which the stakeholders did not identify or, at the time of the survey, could not predict using in the future.

Once the data demand model was established, another round of feedback was undertaken to validate the assumptions. The Data Demand Model was also reviewed and validated as a sound technical approach with Canadian Government scientists.

Several sources were used to determine the application data rates. These are discussed in more detail in §3.3.1.

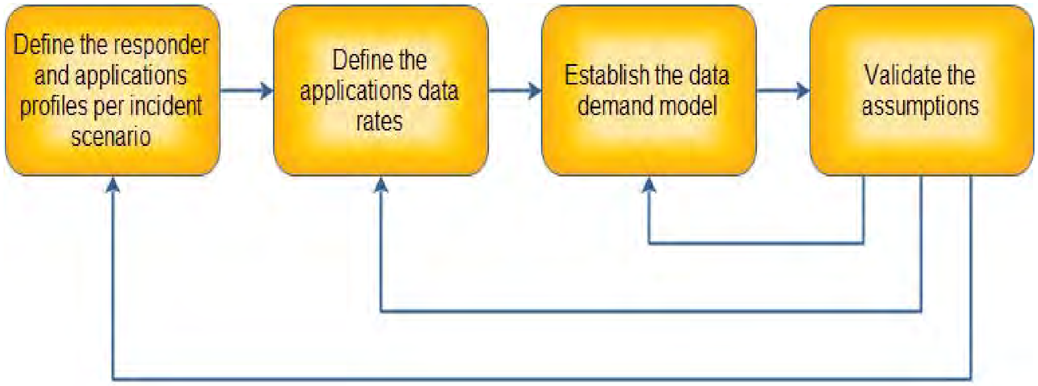

Figure 2.1: Process to develop the Data Demand Model

2.2 Network Infrastructure

The Capacity Model is based on the capabilities of Long Term Evolution (LTE). LTE is the latest generation of mobile broadband technology being deployed by commercial carriers around the world for their 3.9G networks with a migration path to LTE-Advanced (4G). Figure 2.2 illustrates the actual and announced deployments of LTE globally. A large uptake of this technology is expected to drive cost down and provide more incentives for the development of new features and capabilities. In addition, the US Federal Communications Commission (FCC) has recently mandated that public safety broadband networks must use LTE. Canadian public safety can leverage the economies of scale driven by the commercial carriers and be inter-operable with US public safety organizations by selecting LTE as the network infrastructure technology for public safety in Canada.

LTE is currently being deployed commercially at Rel.8 and in pilot stages for a small number of public safety agencies in the US. The 3GPP organization is currently defining Rel.9, 10, and 11. Each successive release introduces new capabilities and especially, improved spectral efficiencies. This is discussed in §4.2.

The Capacity Model and related assumptions were also reviewed in detail with Canadian Government scientists having expertise in the wireless communications domain and the approach was judged to be technically valid and appropriate for the purposes of this study.

Figure 2.2: Locations with actual LTE deployments (blue markers) and announced deployments (red markers) [*]

[*] www.ltemaps.org

3 Demand for mobile data communications

The need for responders to communicate and access information is felt most acutely during the response to an incident. During these events the mobile broadband network will see the greatest demand for data throughput. Figure 3.1 illustrates that an incident is a localized event and so, unlike day-to-day operations where the data demand is spread over a territory that spans multiple cell sites, an emergency event will drive data demand from within a small geographic area.

Although an incident may arise anywhere on land or on water across the entire Canadian territory, this study focuses on the data demands from public safety agencies in a mid-to-large size urban setting. It is assumed that the deployment of a mobile broadband network will launch in urban centers first before expanding to sub-urban and, eventually rural areas. Urban centers will have the greatest density of users and greatest number of recurring events requiring the intervention of public safety and security forces.

It is important that sufficient capacity be available during an emergency event, as well as suitable congestion management policies to effectively deal with peaks in demand that exceed the instantaneous available capacity. The assertion of congestion management mechanisms must not impede the ability of the responders to execute their mission during the events.

In this section the foundation of the Data Demand Model (DDM) will be described. It considers the demand for data communications during an emergency event overlaid on the data demands of day-to-day operations.

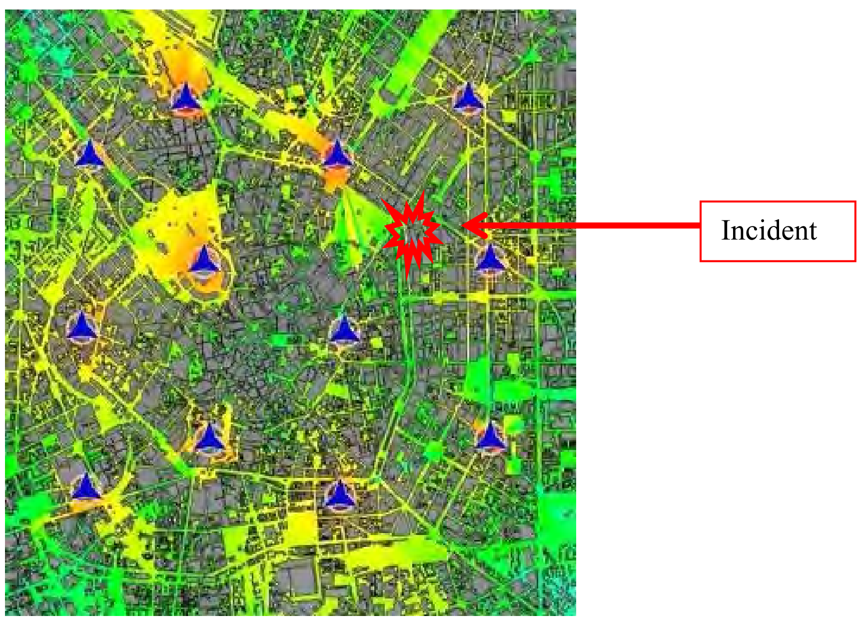

Figure 3.1: Illustration of a localized incident in a multi-cell network deployment.

3.1 Incident scenarios

In consultation with first responder stakeholders and in alignment with similar assessments recently performed in the US, the estimate of the data demands were based on common occurrences and predictable incidents. Three hypothetical, but plausible scenarios have been identified to serve as case studies. These case studies represent events that public safety agencies expect to encounter and for which Standard Operating Procedures (SOP) have been formulated. They are:

- Chemical Plant Explosion and Fire
- A Severe Multi-Vehicle Accident
- Sports Event Riot

A number of representatives of the public safety community from across Canada contributed to defining the nature of the response to each scenario in terms of the number and types of responders and support agencies, and what applications the stakeholders would use during each event. Below are descriptions of the incident scenarios that were used as case studies.

Catastrophic incidents such as a major earthquake or a major terrorist attack are not modelled in this study since the magnitude of the response at that time would overwhelm any mobile data network dimensioned for more routine events such as those which are considered here. Other measures would be required such as diverting or extending capacity from surviving commercial networks.

3.1.1 Chemical Plant Explosion

This case study was adapted from a scenario developed by the Wireless Innovation Forum – Public Safety Special Interest Group* and is based on a hypothetical scenario of a chemical plant explosion, with events drawn from a number of sources including the chemical plant explosion scenario developed as part of the US DHS SAFECOM Public Safety Communications Statement of Requirements/TR-8 Broadband Task Group, and analysis of actual events of the fire at a hazardous waste transfer plant in Apex, NC, in October 2006. This scenario is relevant to other types of incidents such as an explosion at a refinery.

<u>Narrative</u>

A large explosion occurs at a 75,000 sq.ft chemical plant in the industrial area of a mid-sized city. The blast shatters windows of buildings in the immediate vicinity. There are a significant number of casualties both from within the chemical plant and outside. Multiple sensors detect and report the incident to the 911PSAP. Within minutes the 911PSAP is also flooded with calls from motorists, pedestrians, and residents. Soon, commercial cellular networks become overloaded.

Air quality sensors around the area detect hazardous substances emanating from the site of the accident. The wind speed and direction reported from environmental monitoring stations indicate that the chemical plume will drift over a residential area with an elementary school, a high school, a library, a hospital, and numerous retail businesses. As it drifts over roads and highways car accidents ensue and some motorists abandon their cars to escape the plume on foot.

Debris expelled by the explosion damages a nearby electrical sub-station, causing a localized power failure.

* http://www.wirelessinnovation.org

First responders report that a type of liquid is escaping from the chemical plant and flowing into the on-site retention basins. However, the condition of the basins is unknown.

3.1.2 Severe Multi-Vehicle Accident

This case study is based on serious accidents that are likely to occur for any of a number of reasons, such as poor weather, driver fatigue, mechanical failure, etc… This scenario is also relevant for a train derailment, aircraft emergency landing, and other similar situations.

Narrative

It's early winter and the temperature is rising from many days below freezing to settle just around the freezing mark with precipitation turning to ice pellets. Icy patches form on a highway running through a major urban centre and a foggy mist reduces visibility.

The flow of traffic on the icy highway in front of a semi-trailer comes to a rapid halt and the driver realizes he is unable to stop in time to avoid colliding with the cars in front. He attempts to swerve but his tractor regains traction while the trailer does not. The rig jack-knifes and flips over the median finally, landing onto its side on the opposing lanes. Vehicles immediately following the tractor/trailer are unable to stop and collide with it. Others, while swerving to avoid it cause accidents in their adjacent lanes. A similar scene is playing out on the opposite side and an oil tanker is also involved. It has also ended up on it side. Oil is leaking but no fire has started. The trailer has a hazardous products sign on the rear door.

Drivers are injured and some of them are trapped in their vehicles. Other drivers fearing that a fire will start, abandon their vehicles on both sides of the highway and run along the highway's shoulders.

All traffic stops on both sides of the highway.

3.1.3 Sports Event Riot

This case study is based on a riot that arises from a victory celebration of a local sports team. Although the premise is a sports event, the scenario is also relevant for any large event that attracts crowds and protesters with the potential for violence.

Narrative

It's mid-June and we're in overtime of game 7 of the Stanley Cup finals when the unimaginable happens at Maple Leaf Gardens – the home team scores an incredibly fluky goal. After a seemingly interminable moment, stunned audiences explode with joy. Crowds empty into the streets from the Garden, bars, cafes, and homes from all areas of the city. Soon many streets are clogged with people and the downtown core becomes a grid-locked parking lot.

Emotions rise and without notice the celebration turns ugly. Gangs begin to break store-front windows. Looting ensues. Cars are set alight. Riots break out spontaneously in various parts of the downtown core and the rioters quickly move from one area to another. They twitter to help coordinate their movements.

A number of people are injured by flying debris and others are trampled by surging crowds in tight quarters. Some riot police officers and rioters are also injured.

3.2 Day-to-day operations

In addition to demands for data during incidents, mobile data communications plays a vital role during the day-to-day operations for public safety and security, and other municipal and government agencies. It is conceivable that in urban environments these agencies would share a single mobile broadband data network. Some examples of day-to-day operations are:

- Issuing traffic citations
- Fire-fighting
- Health emergencies
- Patrols
- Incident reporting
- Database querying and records look-up
- Work-site inspections
- Maintenance and waste management services
- Public transit
- Utilities: meter reading, service upgrades or restoration

Incidents, when they arise, do not displace day-to-day operations. Incidents occur while day-to-day operations continue.

Table 3.1 illustrates the profiles for the three incident scenario case studies of §3.1 and for Day-to-Day Operations in terms of the number and types of assets that are assigned to each situation. For the purpose of quantifying the number of devices that generate or consume data, this study defines "assets" as vehicles and assumes that data communications devices are detachable so they can be vehicle-borne or person-borne.

3.3 Applications

In a poll conducted among representatives of the Canadian public safety community (municipal police forces, RCMP, Fire Services, Emergency Medical Services, Provincial Emergency Management, and National Search and Rescue), the participants indicated which applications they were likely to use across a mobile broadband data service. The City of New York, in its analysis of 700MHz spectrum requirements, identified a similar set of applications[3]. The candidate applications are listed in Table 3.2. They are broadly categorized as:

- Video Applications
- Collaborative tools
- Monitoring
- Database access and records upload
- Messaging

The same representatives also identified the main applications they were likely to use during emergencies. The results are shown in Table 3.3.

Assets	Chemical Plant	Multi-Vehicle Accident	Sports Event Riot	Day-to-Day Operations

Table 3.3: Association of broadband data applications to public safety assets and direction of data flow.

3.3.1 Applications performance requirements

Table 3.4 lists the data rates used in the Data Demand Model. They are separated into UL and DL directions since the LTE spectral efficiencies are different for UL and DL.

	Datarates (kbps)		
Video applications	DL	UL	
Surveillance video HR	1536	0	streamed to Users on demand
Surveillance video LR	64	0	streamed to Users on demand
Tactical video LR	64	64	distribution of tactical video for composite view; constant streaming
Tactical video HR (monitor)	1152	1152	Viewing video imagery on monitors; per selected feed.
Ambulance patient video (LR)	0	64	distribution of patient video for composite view; constant streaming
Ambulance patient video (HR)	0	768	Viewing video imagery on monitors; per selected feed.
Public Transit video (LR)	64	64	distribution of public transit video for composite view; constant streaming
Public Transit video (HR)	384	384	Viewing video imagery on laptops; per selected feed.
Video conferencing	384	384	per User
News feeds	768	0	streamed to Users on demand.
Collaborative tools	50	50	average data rates per user.
Emergency Management System			
Computer-Aided Dispatch			
Records Management System			
Database access and records upload	50	20	average data rates per user.
GIS information			
still images			
Building plans and information			
Hazmat inventory			
medical records			
NG911 video file (pre-recorded)			
Weather information			
internet access			
Patient triage			
Traffic advisories			
e-Ticketing			
Vehicle Registration			
Biometric data			
License Plate Reader	50	256	
Messaging	40	20	average data rates per user.
SMS			
MMS			
email			
Monitoring	30	60	occurs in the background and is assumed to be a constant rate
Automated Vehicle Locating	5	10	
Blue Force Tracking	5	10	
Vital signs monitoring	5	10	
Automotive telemetry	5	10	
Tracking evacuees	5	10	
CBRNE sensors	5	10	

Table 3.4: Applications data rates (kbps).

The following are the different types of video traffic used in the model:

a) Surveillance video HR: scaled from the Incident Video High Resolution (HR) because of the wider angle scene captured by fixed surveillance cameras. Capable of full-motion 30fps.

b) Incident video HR: based on empirical data used in the report by the City of New York to the FCC. [3]

c) Ambulance Patient Video HR: near-field scene capture.

d) Public Transit video HR: mid-level frame rate 15fps, near-field scene capture

e) Video conferencing: near-field scene, mid-level frame rate15fps.

f) News Feeds HR: lower resolution than surveillance or incident video. Full-motion.

g) LR video (Surveillance, Incident, Patient, and Public transit): low-rate transmission of un-viewed video streams. See §3.3.2.1 for further discussion on dual-rate video.

The US National Telecommunications and Information Administration's (NTIA) recommended minimum data rate for tactical video for Standard Definition viewing is 768 kbps for H.264, also known as MPEG-4 Part 10, or AVC (advanced video compression). [4]

3.3.2 Video traffic management

Video applications represent the largest consumer of capacity on a broadband network. As such, management of this application merits particular attention. In this section we will discuss various approaches to make more efficient use of video applications. The techniques described in the following sections will be used in the Data Demand Model to minimize the bandwidth required by the various video applications.

3.3.2.1 Dual Rate Video

As discussed in §3.3.1 the data rate requirement for video depends on the intended use. For example, a high resolution video would be required to view a wide-angle scene on a monitor and be able to distinguish relatively fine details but a much lower resolution video would be needed for simple traffic monitoring,. Figure 3.2, shows a typical picture of a traffic surveillance camera. In order to read license plates from this scene a much higher resolution stream would be required.

However, it is highly unlikely that video captured at high resolution would be needed continuously for its details. Therefore, in order to limit bandwidth, we include in the Data Demand Model a component for dual-rate video, where the lowest data rate is set to 64Kbps and the maximum rate is as given in Table 3.4 for the different types of video. Dual-rate video is a variation of Adaptive Rate Video currently used by Apple, Adobe, and Microsoft, albeit each with their proprietary algorithms[5]. Although video is sampled at the highest rate possible at the source, it is transmitted at low resolution (LoRes) if it's not viewed.

Figure 3.2: Scene captured from a surveillance camera.

Figure 3.3 illustrates one video stream being viewed, thereby sent at high resolution (HiRes), and three video streams displayed as "thumbnails" which are not actively viewed. The latter are carried across the broadband data network at 64Kbps. In this example if a viewer selects from one of the thumbnail scenes, the selected scene would switch to HiRes mode and the previously viewed one would become a thumbnail and revert to LoRes mode.

Figure 3.3: Illustration of one actively viewed video stream and three "thumbnail" streams

In Figure 3.4 sources V1 and V4 are displayed as thumbnails on viewers M1-M4 only. As such their uplink data rates are 64Kbps, whereas V2 and V3 are viewed in expanded mode so they are uplinked at the HiRes data rates.

The DDM applies a video de-rating factor (VDF_{HiRes}) to the average HiRes video data rate, which takes into account the number of sources of video (VS) and the number of authorized viewing instances (VI). VDF_{HiRes} is expressed in Eq.(1):

$$VDF_{HiRes} = 1 - [(VS - 1)/VS]^{VI} \quad (1)$$

3.3.2.2 Video management policy

Another way to manage video traffic is to limit the number of video sources admitted into the pool of viewable feeds and to limit the number of authorized viewers. This is a policy matter that requires an Operations Support System (OSS) to be able to assign higher priority to some video sources over other sources. For example, in the case study of the Chemical Plant Explosion, video feeds from police cruisers that are re-directing traffic around the affected area may be assigned lower priority than video feeds from fire-fighters.

The OSS would need to permit ad hoc adaptation of the policy to react to evolving circumstances. Following from the previous example, police video feeds may have a higher priority while they are on-route to the incident site and then be assigned a lower priority when the fire-fighters arrive.

The DDM includes a second bandwidth-preserving component by limiting the number of viewable HiRes and LoRes video feeds at any one time. Table 3.5 outlines the video management policy as implemented in the DDM.

Table 3.5: Video Management Policy

	Emergency Operations Centre	Incident Command Vehicles	Authorized First Responders *
Max simultaneous HiRes views	8	2 (each)	1 (each)
Max simultaneous LoRes thumbnails	no limit	10 (each)	3 (each)
Max number of simultaneous video conferencing participants	4	4	4

* not all First Responders would be authorized or equipped to access video feeds. It would be specific to the incident.

3.3.2.3 Multimedia Broadcast Multicast Service

Multimedia Broadcast Multicast Service (MBMS) over an LTE wireless network allows the same video stream to be viewed simultaneously by multiple subscribers with only minimal overhead penalty. One stream consumes capacity in the down-link direction irrespective of the number of simultaneous viewings. [6]

Figure 3.3 illustrates the function of MBMS through an example of 2 downlink users, M1 and M3, viewing the same scene from V2. Only one feed is streamed in the downlink direction to serve 2 simultaneous viewers.

When there are more viewers than sources of video, MBMS can be treated as a gain which reduces the amount of downlink traffic. MBMS Gain is calculated according to Eq. 2.

$$\text{MBMS Gain} = \frac{[\text{\# of viewers}] \times [1 - \text{MBMS overhead}]}{[\text{\# of video sources}]} \qquad (2)$$

where MBMS overhead is 10%.

If the number of sources exceeds the number of viewers, then MBMS gain is set to 1 and MBMS overhead is 0.

MBMS was released by the 3rd Generation Partnership Project [*] (3GPP) as part of Rel.6 (High Speed Uplink Packet Access – HSUPA) in Dec.2004 and further updated in 2009. LTE Rel.9 includes E-MBMS (Enhanced MBMS), which supports multi-cell reception for improved spectral efficiency at cell-edge.

---

[*] www.3gpp.org

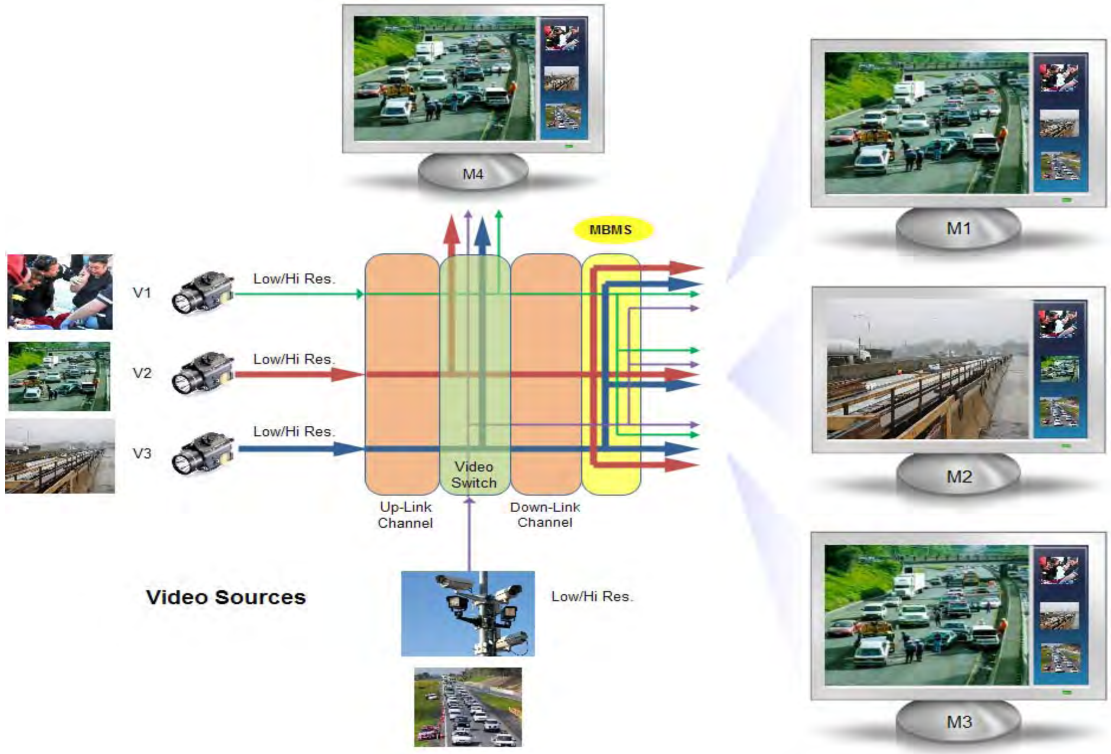

Figure 3.4: Illustration of MBMS function.

3.4 Growth Projections

The global demand for mobile broadband data is experiencing exponential growth in the commercial space fueled primarily by the continued deployment of laptop and netbook computers, and smartphones. Figure 3.5 illustrates the forecasted global demand for mobile broadband data.

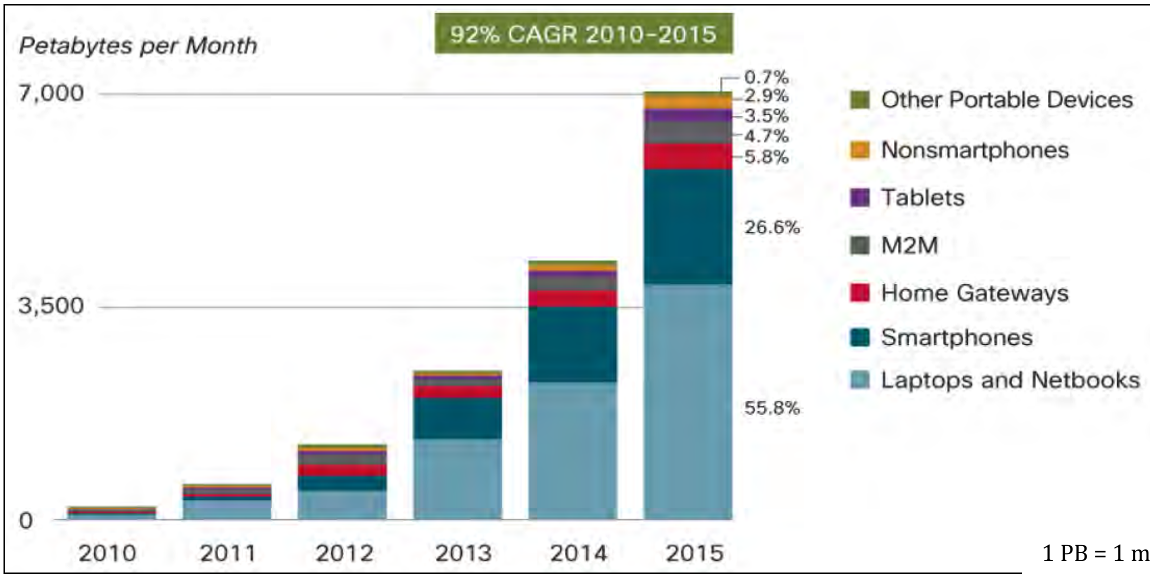

Figure 3.5: Forecasted global demand for mobile broadband data [7].

It is unlikely that public safety's demand for mobile broadband data will experience the same exponential growth, in part because the amount of spectrum allocated for public safety is less than what is allocated for commercial users. Nonetheless, there are growth drivers that will affect public safety's demand for mobile data. For example:

- Adoption rate among public safety agencies of devices which allow access to a mobile broadband network. In a given city, region, or territory the rate at which responders will be equipped with the capability to access a broadband network will be strongly affected by budgets allocated for this purpose.
- Introduction of new applications and tools that have not yet been identified in Table 3.2. Innovative new applications and tools that increase safety, improve the way missions are executed, and increase cost effectiveness are highly desirable. It is foreseeable that public safety agencies will adopt new applications and tools over time as they are vetted for stability, as SOPs are created and validated, and as budgets permit. New applications and tools are expected to increase the data throughput requirements.
- Organic growth of the public safety community in line with the growth of the general population.

The DDM has a growth component in the model to account for the contributing elements above as summarized below.

a) Rate at which public safety agencies will equip their staff with capabilities to access a broadband wireless network: **40% of responders equipped at YR-1 followed by 10% per year incremental growth.**

b) Rate of growth of data throughput required by new applications and tools: **5% per year.** It is assumed that the applications of Table 3.2 will be deployed in the 1st three years and that new applications would be introduced starting in Year-4

c) Organic growth rate of public safety personnel and assets: **3% per year**.

3.5 Data Demand Model (DDM)

The demand model uses the following elements:

a) The number and mix of responders that converge onto typical incidents. Table 3.1.

b) Applications that public safety will likely use with a mobile broadband network. Table 3.2.

c) How the applications are used and by whom. Table 3.3.

d) Applications data rates. Table 3.4.

e) Video Management Policy. Table 3.5.

f) Multimedia Broadcast Multicast Services (MBMS) DL gain.

g) Growth projections according to §3.4

3.5.1 Variables

In addition to the above factors, the DDM uses a number of variables. These are listed below in Table 3.6.

The Statistical Gain (SG) is also referred to as over-booking factor and accounts for the fact that not all Users are accessing data at the same time, thus the sum of the Users' data rates is divided by the SG. The City of New York report states that during an incident, first responders make more intense use of the communication tools and, therefore, use SG = 4, compared to SG = 20 during normal operations.

Typically, SG is a static value that network engineers assign to their dimensioning models. The thesis cited as a reference here proposes an approach whereby SG could be specific to the application[8]. So, some applications would have different SG than others. As shown in Table 3.6, the DDM uses different values of SG, which are:

- SG = 4 for streaming video and interactive applications,
- SG = 10 for video conferencing,
- SG = 1 for monitoring applications.

Table 3.6: List of Variables used in the Data Demand Model.

Video management policy	Incident scenarios	Day-to-Day Operations
Number of simultaneous HR feeds that can be viewed at EOC	8	8
Number of simultaneous LR feeds that can be viewed at EOC	balance of feeds	
Number of simultaneous HR feeds that can be viewed at MCV	2	2
Number of simultaneous LR feeds that can be viewed at MCV	10	10
Number of simultaneous HR feeds that can be viewed by selected 1st Responders	1	1
Number of simultaneous LR feeds that can be viewed by selected 1st Responders	3	3
Number of simultaneous video conferencing participants	4	4
Number of Patient Videos that can be viewed simultaneously at med.ctr.	4	40
Number of fixed Surveillance video cameras (not backhauled with LTE)	4	100
Number of live News feeds	1	6
Multicast Broadcast Multimedia Services (MBMS) overhead	10%	10%
Statistical Gain		
streaming video	4	20
video conferencing	10	20
interactive applications	4	20
background polling application	1	1
Growth variables		
Penetration rate for mobile broadband services (per year)	10%	10%
Growth of the user community - assets and people (per year)	0%	3%
Introduction of new and as-yet uknown applications and devices (annually, after year-3)	5%	5%
Area of Operations		
size of the territory (sq.km)		630
radius of a cell (km)		2
number of sectors in a cell		3

EOC means Emergency Operations Centre.
MCV means Mobile Command Vehicle.

3.5.2 Growth Rate

The growth rate of the data demand is assumed to be 5% per year, compounded annually. This is the same value that is used in the City of New York report, which the authors state as being conservative. In §4 the aspect of error in the estimates will be discussed. The actual increase in demand that will be experienced depends on many variables. Some examples:

- Public safety is currently not using some applications due to limited BW availability. When a broadband network is in place, the experience may be higher than what is assumed in this model.
- New tools will appear that will support different types of responses to incidents or day-to-day use. This could increase the data demands of the response profile in the future.
- Lessons-learned from the response to incidents will lead to changes in Standard Operating Procedures, which could have an impact on how tools and applications are used, which ones are used, at what time, and to what degree of intensity.

The model also assumes that a policy is in place to manage the use of incident video and the consumption of video feeds, in general. Video is the application which demands the most bandwidth and, as such, a video management policy would limit the amount of video transmitted on the wireless network.

The Model does not account for improvement in efficiencies for various applications. For example, video coding has migrated from MPEG-2 to MPEG-4, which essentially improved the coding efficiency by 50%. But, a counter-balancing assumption is that software applications become more complex and less efficient in their performance.

3.6 Data Demand profile

Figure 3.6 shows the DL, UL, and aggregate data demand for the 3 incident scenarios added to day-to-day operations, including the effects of compounded growth in demand.

From YR-1 to YR-10, the growth in demand is dominated by the 10-year capital investment plan to equip public safety. Each year 10% of the user group is equipped, culminating in 100% of the users being equipped in YR-10. From YR-11 to YR-20, the growth in demand is driven by the growth factors discussed in §3.4.

The projected growth of data demand for public safety is in sharp contrast with the projected growth for the commercial segment, as seen in Figure 3.5. Whereas the commercial growth follows an exponential trend, the growth for public safety demand follows a quasi-logarithmic trend. The projected growth in commercial demand fuels a vigorous research environment into methods to be able to cope with the expected demand. This will be discussed further in §4.

Another assumption is that the capital investment to equip public safety with the tools and applications that are considered in this study is made incrementally over a 10-year period, with 1/10th of the investment made each year. The responder profiles and applications in Tables 3.1, 3.2, and 3.3 are for a fully equipped responder community, which corresponds to YR-10 in Figure 3.6.

The responder profiles for each incident case study and application data rates have a strong influence on the demand. The incidents that were selected as case studies could have been different, which would have resulted in higher data demands.

For comparison purposes the City of New York published a demand growth profile and is highlighted in Figure 3.7. Note the inflection in the slope, which indicates that the growth in demand slows down after the inflection point, around year-8.

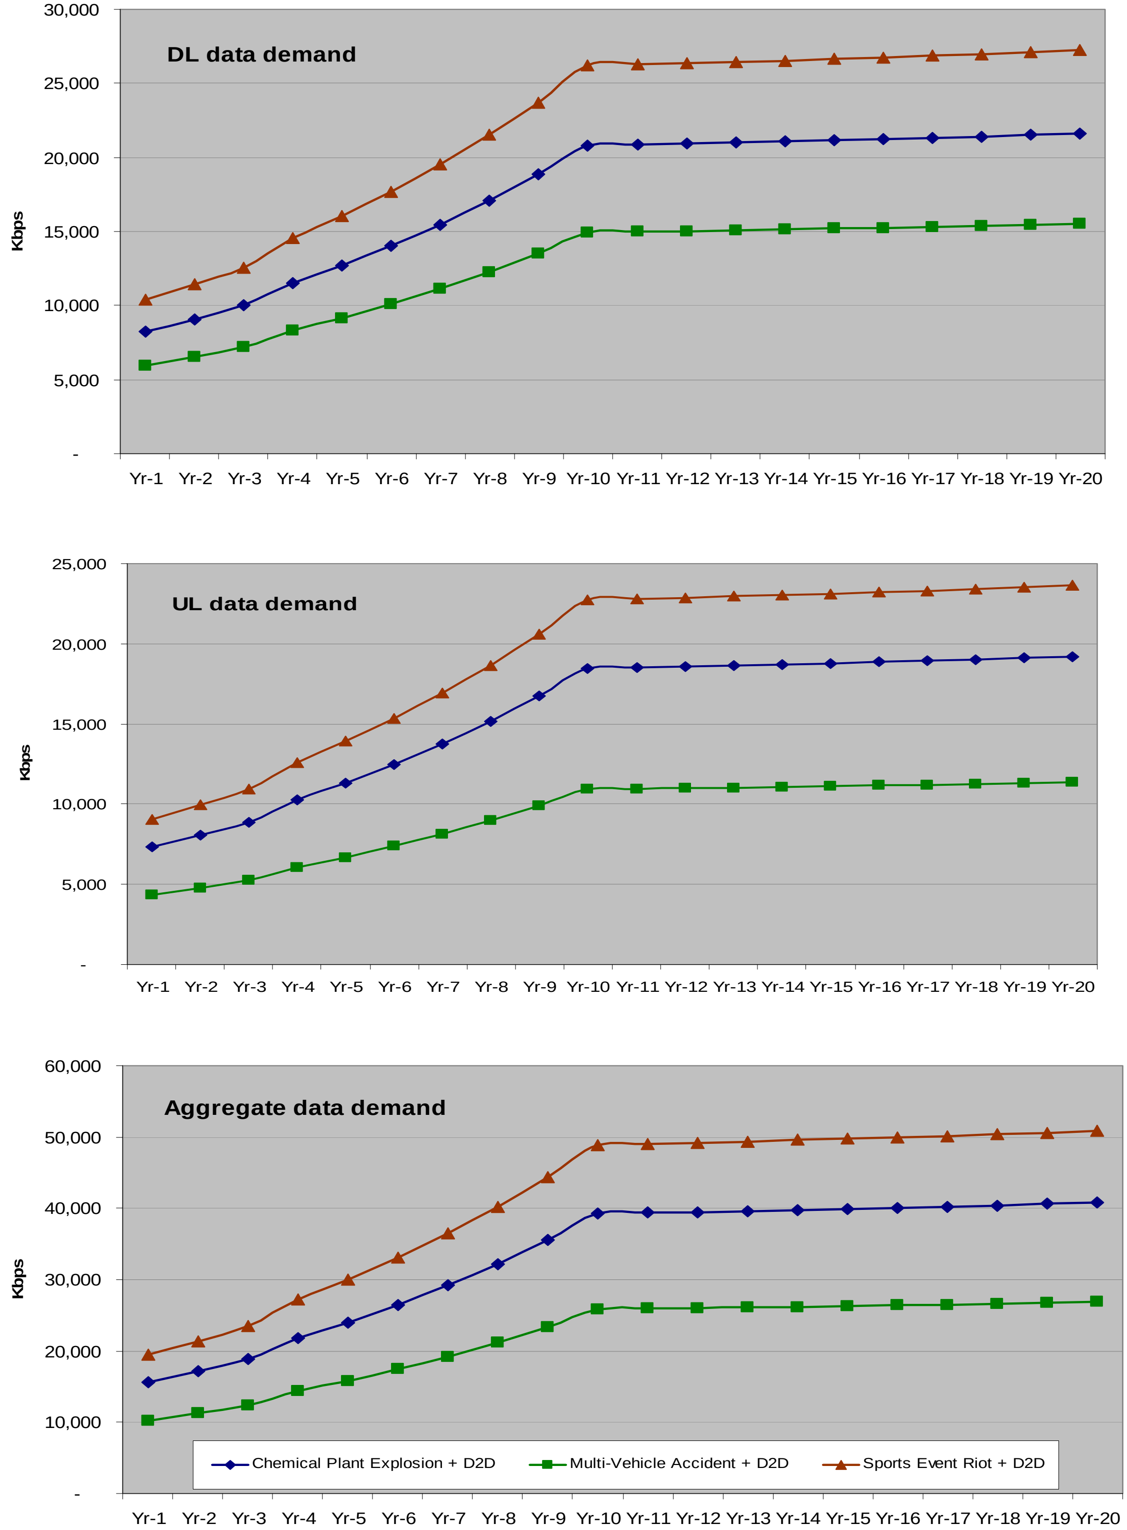

Figure 3.6: Data demand profiles for DL, UL, and Aggregate, including growth effects and day-to-day operations.

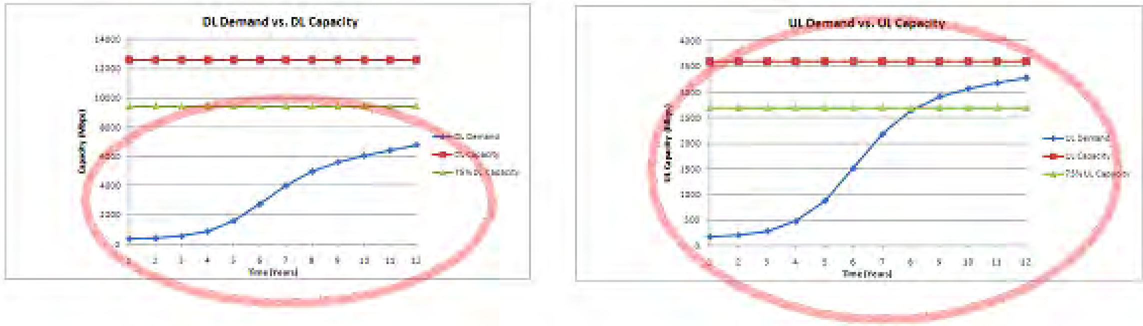

Figure 3.7: Data demand growth profile as reported by the City of New York [3]

4 Capacity model

The Capacity Model establishes how much data can be transported over an LTE system. The model treats Up-Link and Down-Link directions separately since LTE spectral efficiency is asymmetric. The 3GPP has released specifications for Rel.8 and 9, and there is on-going work to define the specifications for Rel.10 and 11. There is also substantial research activity at university and industry levels on ways to improve efficiencies. New features for LTE will one day be implemented and the benefits will be realized, perhaps not to the same extent as predicted, but we can reasonably expect the capacity to increase as the vendor community transforms the research into commercially viable products.

Some technologies, currently under development or the subject of research, were examined for their potential to increase spectral efficiency. Based on these, a hypothetical technology roadmap was established in order to quantify spectral efficiency improvements in the Capacity Model. The various technologies that were examined are described in §4.3.

In §4.4 are the basic assumptions that are considered in the Capacity Model.

4.1 Long Term Evolution (LTE)

Long Term Evolution is the latest standard for mobile wireless access from the same industry group that developed the specifications for GSM and UMTS/HSPA, namely 3GPP. LTE improves upon the performance of previous generations of wireless systems in terms of increased capacity, reduced latency, and support for multimedia applications. Its current release, Rel.8, is referred to as 3.9G. LTE-Advanced (Rel.10) with even superior performance is intended as the first release to cross the threshold into 4G. Some of the key specifications are:

- Peak downlink data rates: 326 Mbps (4x4 MIMO [1]); 173 Mbps (2x2 MIMO) in 20 MHz bandwidth.
- Peak uplink data rates: 86 Mbps with a single transmit antenna in 20 MHz bandwidth.
- Latency: 5ms or less.
- Backwards compatible with: GSM, CDMA-One, UMTS, and CDMA2000
- Able to operate in Frequency Division Duplex (FDD) and Time Division Duplex (TDD) modes.
- Able to operate in carrier bandwidths of 1.4MHz, 3MHz, 5MHz, 10MHz, and 20MHz.
- Frequency bands: as shown in Table 4.1 for FDD and Table 4.2 for TDD[*]

[*] TDD approved in Europe, China, India, Japan, Malaysia, Australia.

Table 4.1: LTE frequency bands for FDD

LTE BAND NUMBER	UPLINK (MHZ)	DOWNLINK (MHZ)
1	1920 - 1980	2110 - 2170
2	1850 - 1910	1930 - 1990
3	1710 - 1785	1805 -1880
4	1710 - 1755	2110 - 2155
5	824 - 849	869 - 894

39	1880 - 1920
40	2300 - 2400
41	3400 - 3600

4.2 The concept of Spectral efficiency

Spectral Efficiency (SE) is a measure of how much information can be carried in a transmission bandwidth normalized to 1Hz, expressed in bps/Hz. It is the key parameter by which to determine the capacity of a wireless network. SE is a function of the signal to noise ratio (SNR) because a higher SNR allows the signal component to occupy more states and thus carry more information. Figure 4.1(a,b) illustrates a sample constellation of signal states for 16QAM and 64QAM modulation. 64QAM can transport 50% more information than 16QAM, but due to the higher density of signal states, 64QAM requires a higher SNR than 16QAM. This is why User Element (UE) which are closer to the base station can support a higher data rate. Since SNR is lower at greater distances from the transmitter, UEs which are at the cell edge have lower data rates.

Spectral Efficiency is also affected by interference. Similarly to noise, interference reduces the space between signal states and leads to a higher probability of incorrectly detecting the instantaneous state of the received signal. In cellular networks interference is a major impairment to spectral efficiency and is the subject of significant research for ways to mitigate its negative effects on SE. However, the effort to improve SE by increasing SNR delivers correspondingly fewer gains relative to the increases in SNR since SE has a logarithmic relation to SNR. Claude Shannon in his seminal paper on the Theory of Communications [1] postulated the mathematical relationship between channel capacity and SNR. His theory is illustrated in the graph of Figure 4.2. SNR is expressed as Eb/No which is the normalized form for SNR.

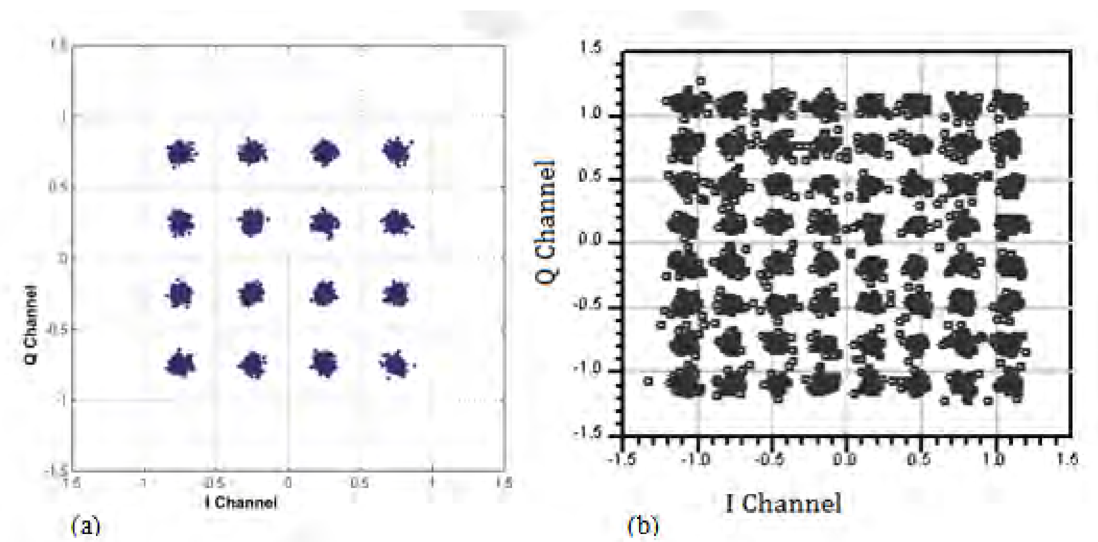

Figure 4.1: Signal state constellation diagrams for (a) 16QAM and (b) 64QAM with noise-induced impairments.

.

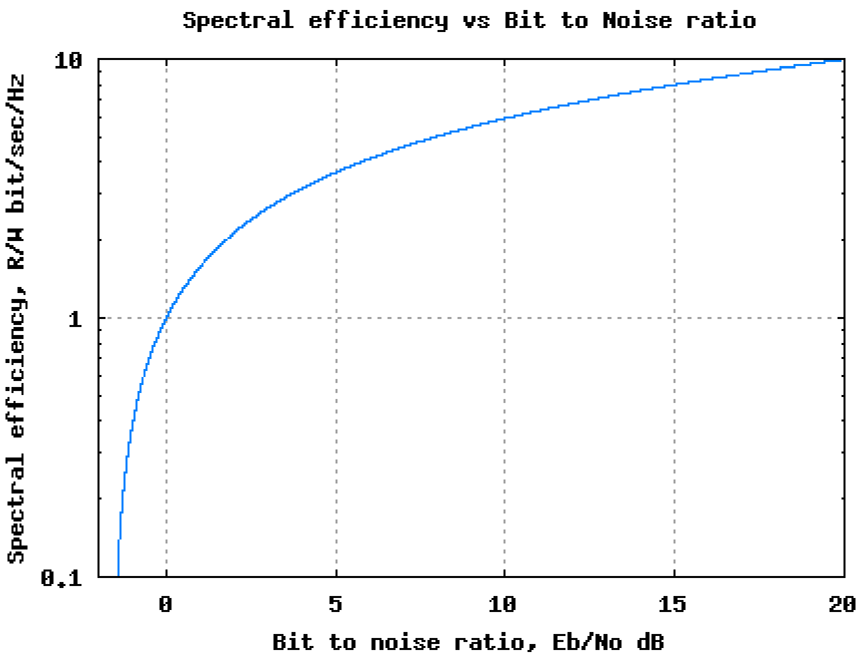

Figure 4.2: Relationship between Spectral Efficiency and Signal-to-Noise Ratio.

4.2.1 Interference effects

Inter-cell interference is one the most important factors limiting the spectral efficiency of a cell. When interference power is combined with Additive White Gaussian Noise (AWGN), the Signal to Interference + Noise Ratio (SINR) ratio is reduced. A User Element (UE) with low SINR means that it must operate at a lower modulation index to keep packet error ratios to an acceptable level for the applications used by the particular UE. A lower modulation index means that the spectral efficiency is reduced for that UE, which in turn reduces the average spectral efficiency for the cell. In essence, higher interference lower SINR lower modulation index lower spectral efficiency.

Figure 4.3 illustrates a typical case where interference triggers the hand-off of the UE from one base station (eNB) to anther eNB. As the UE moves away from its serving eNB, the signal power of the serving source reduces, while the signal power of the adjacent eNB increases. While the UE is still served by the left-hand eNB, the signal from the right-hand eNB appears as interference. Thus the UE experiences a reducing SINR (reducing spectral efficiency) as it moves towards the cell edge. The hand-off process is initiated when the SINR reaches a threshold point.

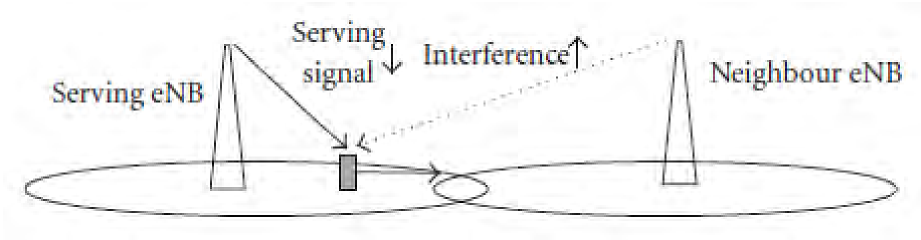

Figure 4.3: Reducing SINR as the UE moves towards the edge of the serving eNB [10].

Interference effects are more significant at cell edges and where cell sectors overlap. A typical cell would be configured into 3 or 6 sectors. Figure 4.4(a) illustrates a 3-sector cell.

One approach cellular network engineers use to mitigate interference is to assign different frequencies to adjacent sectors. In Figure 4.4(b) the Frequency Re-use (FR) factor is 3, but in practice may be as high as 7. The consequence of this approach is to assign 1/3 to 1/7 of the RF spectrum to each sector. Each sector would then have 1/3 to 1/7 of the aggregate throughput.

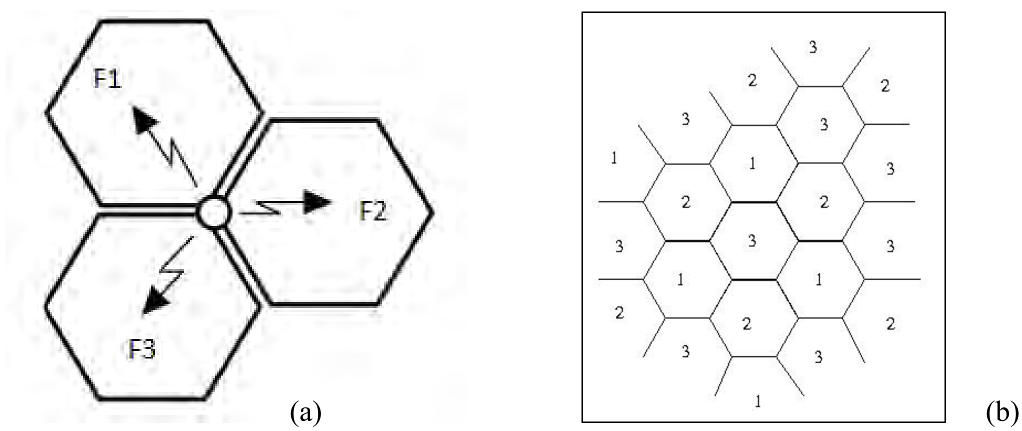

Figure 4.4: (a) frequency assignments in a 3-sector cell with FR = 3; (b) network frequency assignments for FR = 3.

Maximizing throughput by various interference mitigation strategies is a rich area of study and will be examined further in this section. The sections that follow review some of the technologies more frequently found in technical literature and oft-cited research.

4.3 Spectral Efficiency Roadmap

Each new generation of wireless technology improves upon the capacity of the previous one. LTE, currently at Rel.8 and Rel.9, will continue to evolve new capabilities into Rel.10, 11, and beyond. Some of the new capabilities will increase spectral efficiency. The Capacity Model assumes a progressively increasing spectral efficiency. Some of the technologies currently under development or in early stages of research are discussed below. Their potential impacts on spectral efficiency are included in the Capacity Model as illustrated in Table 4.3. The SE Roadmap is specific to the Capacity Model. The actual sequence of technology deployment may differ from that shown in the table or the values of SE may also be different.

Table 4.3: Spectral Efficiency Roadmap specific to the Capacity Model.

	T0: YR1-3	T1: YR4-6	T2: YR7-9	T3: YR10-12	T4: YR13-15	T5: YR16-18	T6: YR19-20
bps/ Hz	**LTE Rel.8**	**Fractional Frequency Reuse**	**Adaptive Fractional Frequency Reuse; 4x4 MIMO**	**Multi-User MIMO**	**Cooperative Multi-Point**	**Dirty Paper Coding**	**Femto-cells Relays**
DL	0.686	0.860	1.060	1.329	1.923	2.398	2.849
UL	0.300	0.375	0.457	0.652	1.051	1.485	1.737

4.3.1 Fractional Frequency Reuse

One of the most active areas of research is to increase the throughput of LTE systems by mitigating the effects of inter-cell interference. Inter-cell interference is a dominating factor in limiting the throughput. An important goal is to reduce the FR factor to as near unity as possible. Figure 4.5 illustrates that with FR=1 the network bandwidth is essentially available in each sector. With FR=3, the network BW is divided by 3. Fractional Frequency Reuse (FFR) is made possible by the X2 communications link between LTE base stations. The mechanisms that are applied in a coordinated manner between eNBs are known collectively as Inter-Cell Interference Coordination (ICIC). ICIC-enabled FFR can achieve lower values of FR such as 3/2 as illustrated in Figure 4.6.

FR factor affects the total network capacity (TNC) as in equation (3). A lower value of FR increases total network capacity.

$$\text{TNC} = \frac{[\text{\# of cell sites}] \times [\text{\# of sectors/site}] \times [\text{SE}] \times [\text{available BW}]}{\text{FR}} \tag{3}$$

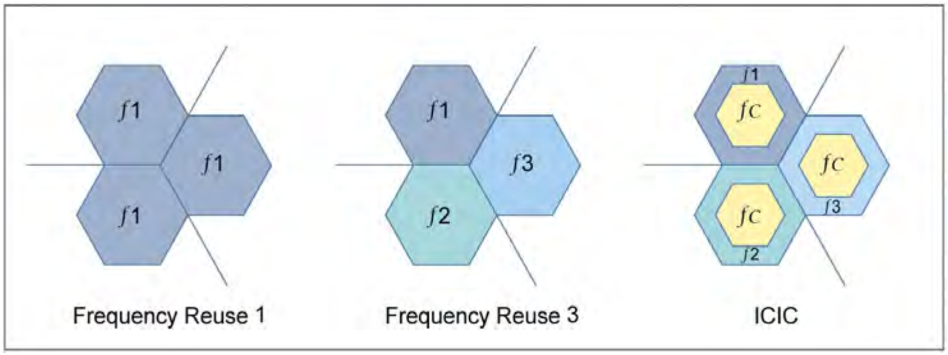

Figure 4.5: Frequency re-use plans FR=1, FR=3, and Fractional Frequency Re-Use (FFR).[11]

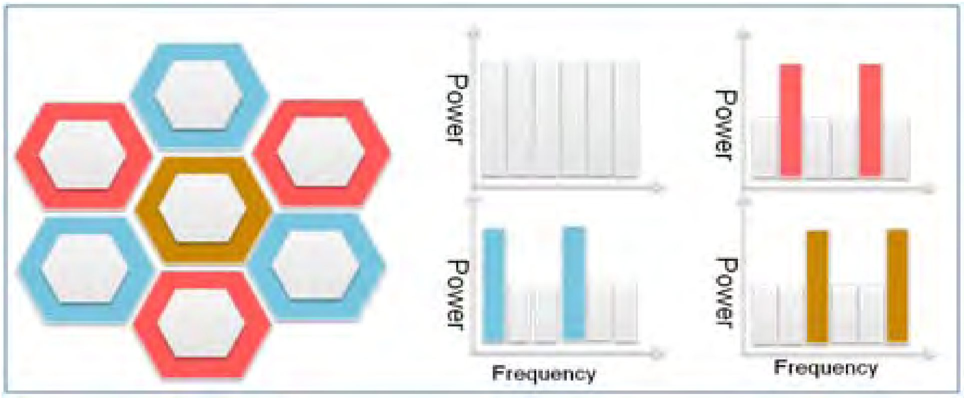

Figure 4.6: Illustration of FR=3/2 using ICIC and associated Power Bandwidth Profiles.

Adaptive Fractional Frequency Reuse (AFFR) is a closed-loop scheme that uses the Channel Quality Indicator feedback from the UE in order to dynamically adapt the scheduling, power level, and channel assignment to the UEs. In addition, AFFR coordinates the actions among all the adjacent eNBs. Simulation results indicate that near unity FR can be obtained. See Table 4.4 for a comparison of simulated LTE sector throughputs for N=1 and AFFR. In the cited article, N ≡ FR. AFFR achieves 99% of the throughput of FR=1.

Table 4.4: comparison of simulated LTE sector throughputs for N=1 and AFFR [12]

	FR =1	AFFR
Sector Throughput (Mbps)	8.01	7.89

4.3.2 Multiple Input Multiple Output (MIMO) techniques

MIMO techniques are used to improve SE. One MIMO scheme, referred to as Spatial Multiplexing (SM), can be used to transmit multiple information streams simultaneously from eNB to the UE. MIMO is also used to cancel interference on streams carrying the same information. LTE Rel.8 is able to dynamically adapt the MIMO scheme in order to maximize throughput using feedback from the UE. This is known as Closed Loop MIMO (CL-MIMO). Figure 4.7 illustrates 2x2, 3x2, and 4x4 MIMO configurations.

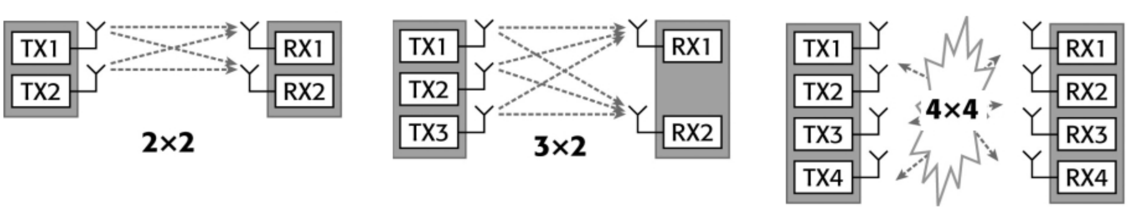

Figure 4.7: Transmitter and receiver arrangements for 2x2, 3x2, and 4x4 MIMO.

Table 4.5 refers to SU-MIMO (Single User MIMO). In this arrangement, the eNB transmits on multiple antennas, whereas the UE transmits on one antenna but receives on multiple antennas. The SE for 2x2 and 4x4-MIMO is given in Table 4.5.

Table 4.5: Average spectral efficiencies for down-link and up-link for 20MHz bandwidth [13] [14]

Down-Link	Spectrum Efficiency		Mean User Throughput		Cell-Edge User Throughput		
	[bps/Hz/cell]	x UTRA	[bps/Hz]	x UTRA	[bps/Hz]	x UTRA	
E-UTRA 2x2 SU-MIMO	1.56	x3,0	0,16	x3,0	0,04	x2,3	Rel.8
E-UTRA 4x4 SU-MIMO	2.41	x4,6	0,24	x4,6	0,08	x4,8	Rel.10

Up-link	Spectrum Efficiency		Mean User Throughput		Cell-Edge User Throughput		
	[bps/Hz/cell]	x UTRA	[bps/Hz/user]	x UTRA	[bps/Hz/user]	x UTRA	
E-UTRA 1x2	0.681	x2.2	0.068	x2.2	0.0044	x2.0	Rel.8
E-UTRA 1x4	1.038	x3.3	0.104	x3.3	0.0094	x4.2	Rel.10

Figure 4.8 compares average spectral efficiencies across different channel bandwidths. The spectral efficiency for 10MHz bandwidth is ≈98% of that for 20MHz bandwidth.

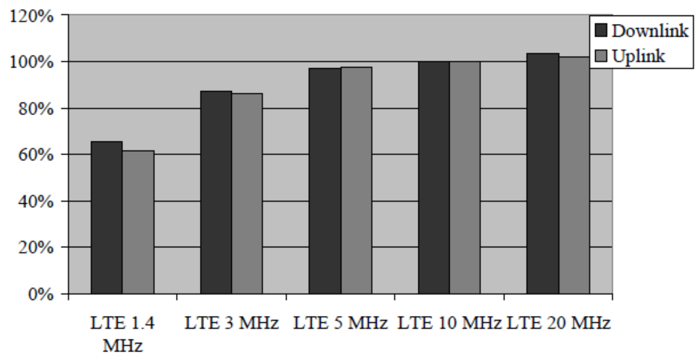

Figure 4.8: Comparison of spectral efficiencies relative to 10MHz channel bandwidth[15].

4.3.3 Multi-User MIMO Uplink

Multi-User MIMO-UL (MU-MIMO-UL) is the equivalent of spatial diversity in the Uplink direction. As in the previous case, interference is estimated from the received signals using Successive Interference Cancellation . Figure 4.9 illustrates a block diagram for the MU-MIMO-UL. Note the feedback from the UE towards the eNB.

This technique can provide ≈ 70% improvement in UL spectral efficiency relative to LTE Rel.8. Refer to Figure 4.10 for a comparison of various techniques being researched by Deutsche Telkom Laboratories to improve SE.

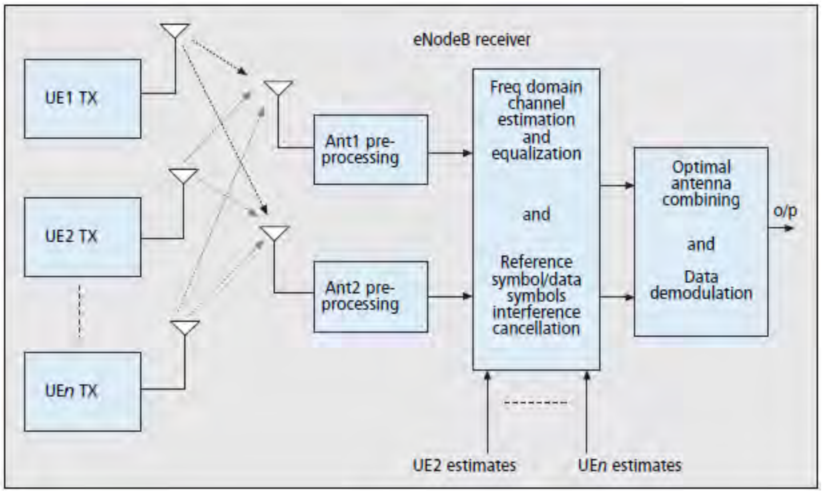

Figure 4.9: MU-MIMO-UL block diagram [12]

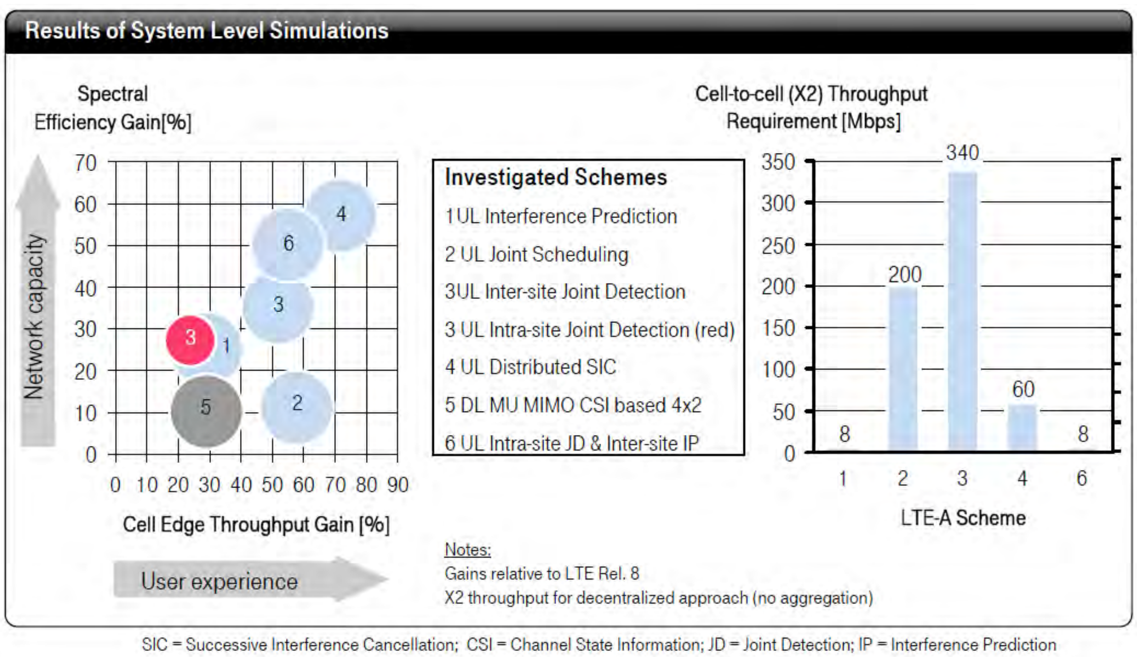

Figure 4.10: Spectral Efficiency Improvements under study. [17]

4.3.4 Multi-User MIMO Downlink, Coordinated Multi-Point

Coordinated Multi-Point (CoMP) with Organized Beam-forming improves the SE at the cell-edge. The average cell throughput is also increased. In organized beam-forming eNBs exchange scheduling and beam-forming information so that multi-site scheduling can be performed. This reduces inter-cell interference. Figure 4.11 illustrates the principle of CoMP. Simulation shows that SE in the DL can be improved by up to 1 bps/Hz using this technique..

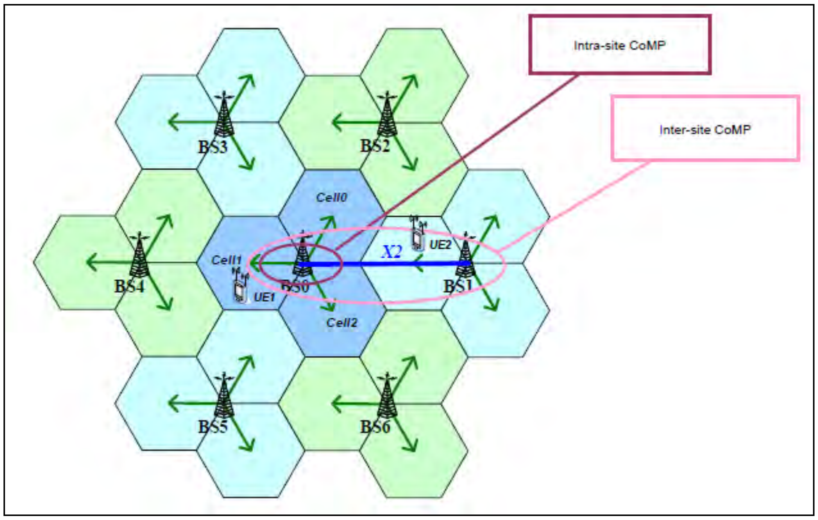

Figure 4.11: Coordinated Multi-Point conceptual diagram [18].

4.3.5 Dirty Paper Coding

Dirty Paper Coding (DPC) is a technique whereby the data is pre-coded at the transmitter using interference information fed back from the UE on the side channel referred to as Channel State Information (CSI). In essence, the transmitter adapts to the interference. Information theorists have presented mathematical arguments that DPC with CSI feedback can approach the performance of Gaussian Noise channels, thereby almost completely cancelling the interference. [19]

Other researchers arrived at numerical results which indicate that DPC can improve the SE of 2x2 MIMO systems by up to 0.8 bps/Hz, and improve the SE of 4x4 MIMO systems by up to 1.35 bps/Hz. [20]

4.3.6 Femto-cells and decode/forward Relays

Femto-cells and relays are used to increase the capacity in a specific location such as malls and conference centres. Femto-cells off-load traffic from the macro node. Relays are used to fill in gaps in coverage from the macro node. See Figure 4.12 for an illustration of the use of Femto cells and Relays.

Both approaches increase capacity although it can be difficult to quantify in general terms since the actual gain is implementation-specific. The Capacity Model assumes a 10% increase in UL and DL SE through the use of Femto-cells and Relays.

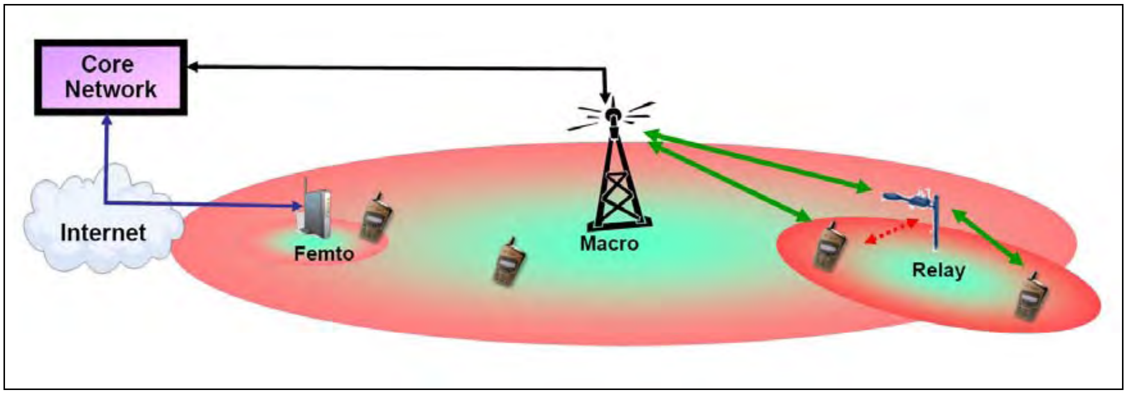

Figure 4.12: Femto cells and Relays used to augment the capacity of a Macro cell.

4.4 Input data and assumptions

The following input data and assumptions and have been used in the Capacity Model.

1. Spectral efficiencies stated in Table 4.5 represent the average of reported results from a number of LTE system and sub-system vendors. They are:
   - Alacatel-Lucent
   - Huawei
   - InterDigital
   - Motorola
   - NEC
   - Nortel
   - Nokia-Siemens
   - Samsung
   - Qualcomm
   - Texas Instruments

2. The introduction of new technology into a network will likely encounter implementation issues and the Capacity Model assumes that there will be a gap between anticipated SE improvements vs. realized improvements. However, the Model also assumes that the gap will reduce in time as the technology matures and implantations issues are worked out. Therefore, the Model applies a de-rating factor to the SE according to the profile: 33%, 25%, 10%, 5%. This means the SE improvement is de-rated by 33% when first introduced, 25% after 3 years, 10% after 6 years, and 5% after 9 years. The un-derated SE values are in Table 4.6. These values are not used in the Capacity Model, but serve as baseline from which de-rating factors were applied.

3. New technology is introduced in the LTE network in 3-year intervals. Even though some technology could be available sooner than it is introduced in the Model, it is assumed that budgets will constrain the ability to procure and update existing facilities. Another assumption is that public safety agencies will be somewhat conservative in upgrading. There will also be some time spent to pilot the upgrades before introducing them into live networks.

4. It is assumed that an incident is a localized event that would be contained geographically within one sector.

5. For FR=3 and FFR, an overlap of 25% is assumed between adjacent sectors. When AFFR is introduced the Model approaches FR=1 and as such no additional capacity is factored into the Model due to overlapping sectors since closed-loop ICIC mechanisms are intended to avoid duplicate scheduling of UEs.

6. SE is a dependent upon the speed of the UE. The Model assumes that the speed of most responders is <3kph at the scene of the incident. LTE SE is higher for lower speeds.

Table 4.6: Un-derated Average Spectral Efficiency (b/s/Hz/sector) not used in the Capacity Model.

	T0	T1	T2	T3	T4	T5	T6
DL	1.529	1.529	2.362	2.362	3.543	3.543	3.897
UL	0.667	0.667	1.017	1.729	1.729	2.729	3.002

5 RF spectrum requirements

This section discusses the results of correlating the data demand with capacity, which is the RF spectrum (bandwidth) required for public safety. It presents the nominal bandwidth and the error introduced by the uncertainty of future predictions. In §5.2 a sensitivity of the bandwidth is analyzed as a function of two key variables. There is also an analysis which presents to what degree public safety would have to back off their requirements in order for 5+5MHz to satisfy the reduced requirements.

Figure 5.1 is an illustration of the growth of data demand (from Figure 3.6) compared to the growth of Spectral Efficiency (from Table 4.3), with YR1 as the reference point. The difference in the growth rates is notable. Given the pressures that commercial carriers face due to the exponential nature of the growth in demand they are experiencing (see Figure 3.5) from commercial users, with no sign of abating, it is expected that they will continue to invest in new technologies to cope with the anticipated growth in data demand. In fact, there is an intense level of research into improving the spectral efficiency of mobile broadband networks 10. The cited article cites a further 64 references.

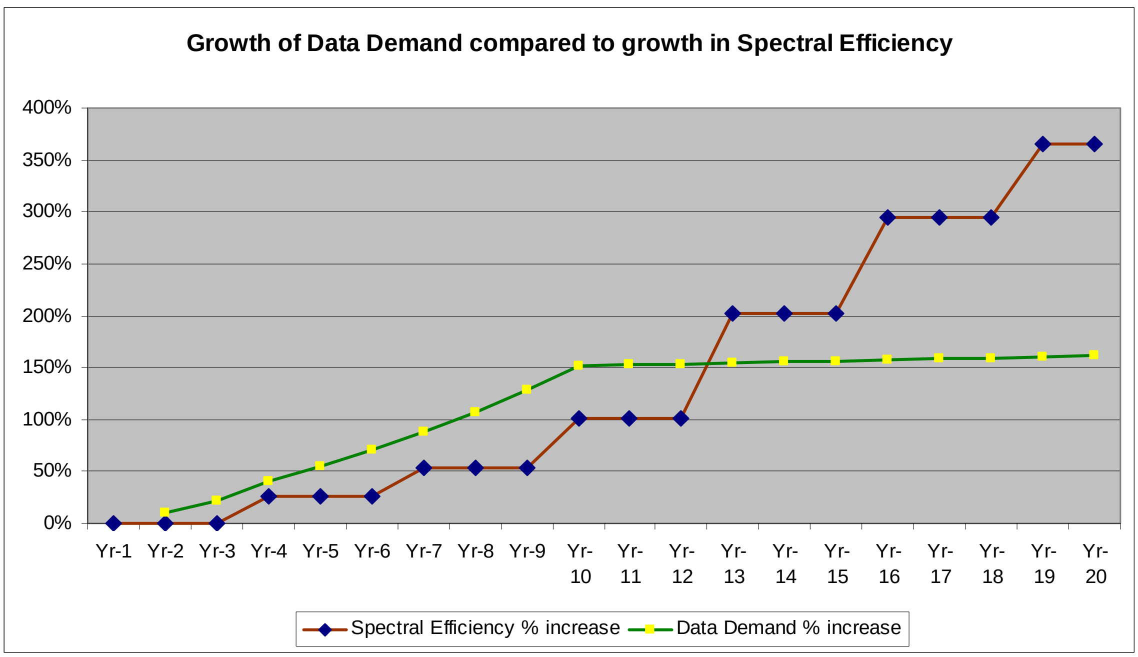

Figure 5.1: growth of data demand compared to the growth of spectral efficiency

It is very difficult to predict what will happen in the future, especially over a 20-year period. Even though it may be easier to predict what the demand could be in the next 1 or 2 years, or what technology would likely be developed in the near-term, there is nonetheless an uncertainty in whatever prediction is made. The degree of uncertainty becomes larger for prediction-horizons that are further out in time.

The Capacity Model has factored an estimating error into the predictions for RF spectrum. Figure 5.2 shows the same growth projections as in Figure 5.1, but also shows the effect of uncertainty using a 10% annually compounded estimating error for demand and the same for SE.

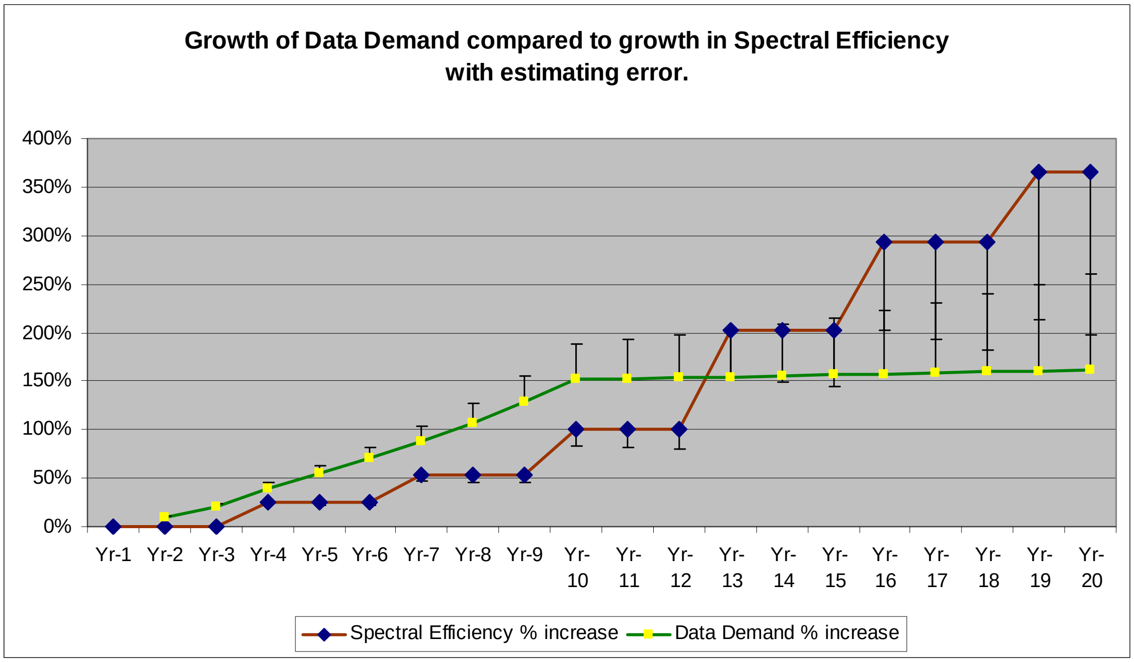

Figure 5.2: Growth of demand and SE with 10% annually compounded estimating error applied to demand and SE.

5.1 RF spectrum requirements – results

This section presents the bandwidth requirements using the inputs below. Alternative scenarios based on sensitivity to SE and SG are examined in §5.2.

(i) Data Demand profiles as shown in Figure 3.6,

(ii) SE values from Table 4.3,

(iii) Estimating error due to uncertainty of predicting future events as shown in Figure 5.2.

Equation (4) is used to calculate the aggregate required bandwidth (BWr):

$$BWr\ (MHz) = \frac{\text{DL Data Demand (kb/sec)}}{\text{DL SE (b/sec/Hz) x 1000}} + \frac{\text{UL Data Demand (kb/sec)}}{\text{UL SE (b/sec/Hz) x 1000}} \qquad (4)$$

Figure 5.3(a,b,c) shows the RF spectrum required for an LTE network to provide sufficient throughput to support the data communications needs for the 3 incident case studies, namely Chemical Plant Explosion, Multi-Vehicle Accident, and Sports Event Riot, respectively. The graphs also show the influence of estimating error. In each graph two curves are shown: one curve for the RF Spectrum required to support the aggregate (UL+DL) data demands for the specified incident, and one curve for the aggregate Usable BW based on a 10+10MHz allocation.

Since an incident is a localized event, only one sector's capacity is available, plus the overlap from the adjacent sector. At the outset, the usable capacity within one sector in either UL or DL direction is the Network capacity (based on 10+10MHz) ÷ 3 (FR) x 1.25 (sector overlap) x 75% (frequency re-use efficiency). If 20MHz is allocated, then only 6.25MHz is actually usable in a sector until further improvements in Frequency Reuse are implemented. The Model assumes that, over time, 95% of the Network capacity becomes available within a sector.

The period where RF spectrum requirement increases (YR1-10) is dominated by investments in LTE UE for the User community. Once the user community has been fully outfitted with LTE UE devices, the subsequent period (YR11-20) is dominated by investments in the LTE eNB infrastructure. These investments are characterized as improvements in spectral efficiency. The effect of introducing improvements in SE can be seen in the graphs as step-wise reductions in required bandwidth.

The following conclusion can be drawn from Figure 5.3:

1. Improvements in spectral efficiency outpace the growth in demand and so it is expected that the applications will require progressively less bandwidth when the penetration of LTE devices in the public safety community has saturated and the investments are turned towards accelerating the improvements in the infrastructure. According to Figure 5.3, the saturation point is at YR10.

2. 10+10MHz (UL+DL) is insufficient spectrum in both UL and DL to meet the data communications needs of public safety during commonly recurring incidents, given the anticipated spectral efficiency of LTE for the near-to-mid term.

3. When LTE technology becomes more spectrally efficient, 10+10MHz could be sufficient spectrum to support the data communications requirements for less severe incidents. This may occur beyond YR15 for benign incidents such the multi-vehicle accident.

4. When estimating error is included, 10+10MHz is insufficient spectrum for all cases throughout the 20-year horizon.

5. There is a significant gap between required spectrum and usable spectrum. During the events of the nature considered in this study, public safety will most likely not be able to use all the applications they identified, nor in the manner in which they expect to use them. In order to deal with situations where demand exceeds capacity bandwidth management policies will need to be established, access privileges would need to be asserted, controlled and monitored, and the use of applications will need to be prioritized. The policies and procedures could be re-visited over time as greater efficiencies are introduced into the network.

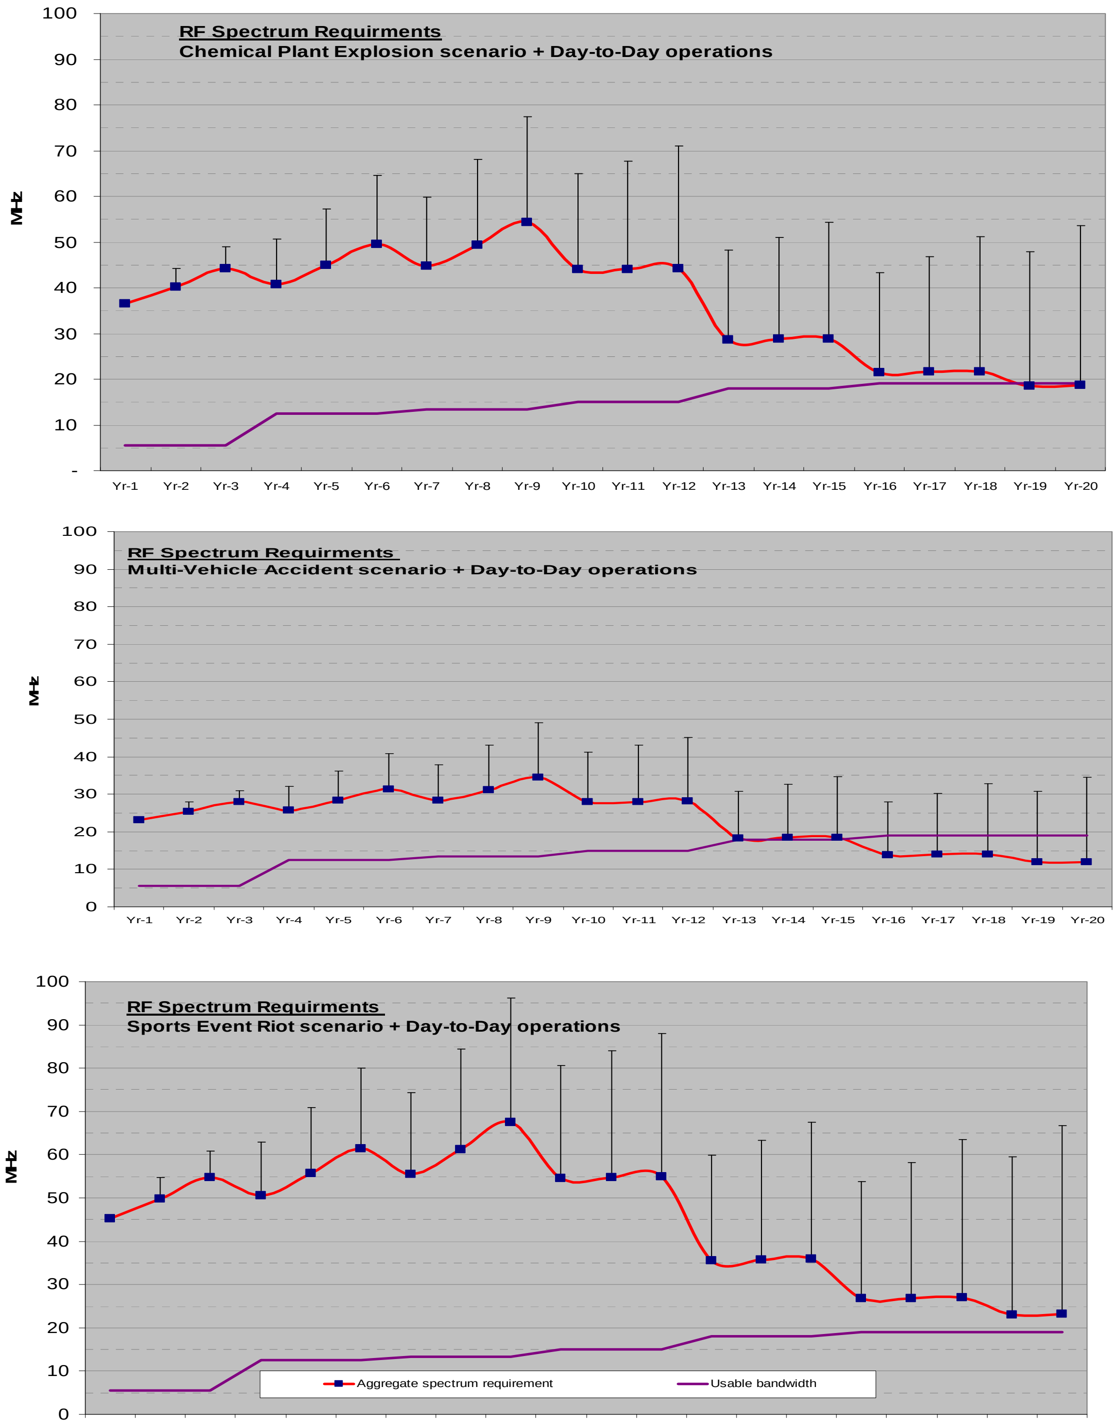

Figure 5.3: Aggregate (UL+DL) RF Spectrum requirements

5.2 Alternative scenarios

The effects of varying some key parameters on RF spectrum requirements will be examined in this section. Two cases examine the effects of aggressive approaches to dimensioning the network. Of course, the results show that less RF spectrum is needed. However, the conclusions of §5.1 remain essentially the same. The only exception would be for less severe incidents, where 10+10MHz would likely be sufficient when technology improves, but 5+5MHz would likely be insufficient.

A third scenario examines how aggressively the parameters need to be adjusted in order to reduce the data demand such that all three incident case studies can be fulfilled with 5+5MHz of RF spectrum.

5.2.1 Accelerated introduction of higher spectral efficiency.

In the Model, de-rated SE values are used to account for slower adoption of new technology in public safety networks due primarily to more restrictive budgets in municipalities or government than in commercial carriers. Public safety will likely have a longer vetting process before adopting new technologies. There would also be less economic/business pressure to upgrade the technology in public safety than in commercial networks.

If the public safety network were to be upgraded at the same pace as a commercial network, this scenario examines the effect of optimistic values of spectral efficiency on required RF spectrum. The un-derated SE values of Table 4.6 are reproduced below. The resulting required RF spectrum is shown in Figure 5.4 (a,b,c).

(copy) Table 4.6: Un-derated Average Spectral Efficiency (b/s/Hz/sector) not used in the Capacity Model

	T0	T1	T2	T3	T4	T5	T6
DL	1.529	1.529	2.362	2.362	3.543	3.543	3.897
UL	0.667	0.667	1.017	1.729	1.729	2.729	3.002

5.2.2 Lower intensity of use of the network.

A key factor in the data demand model is the over-booking factor (OBF). Since first responders will make more intense use of their data communications tools during an incident than during non-emergency situations, the Model uses an OBF ratio of 4:1 for streaming video and interactive applications. Commercial users also make more intense use of the network during emergencies. During these events typical OBF ratios of 20:1 or 50:1 for commercial users no longer apply.

Nevertheless, in this scenario the OBF for streaming video and interactive data is doubled from 4:1, as in the Model, to 8:1. The results for the three incidents case studies are illustrated in Figure 5.5(a,b,c).

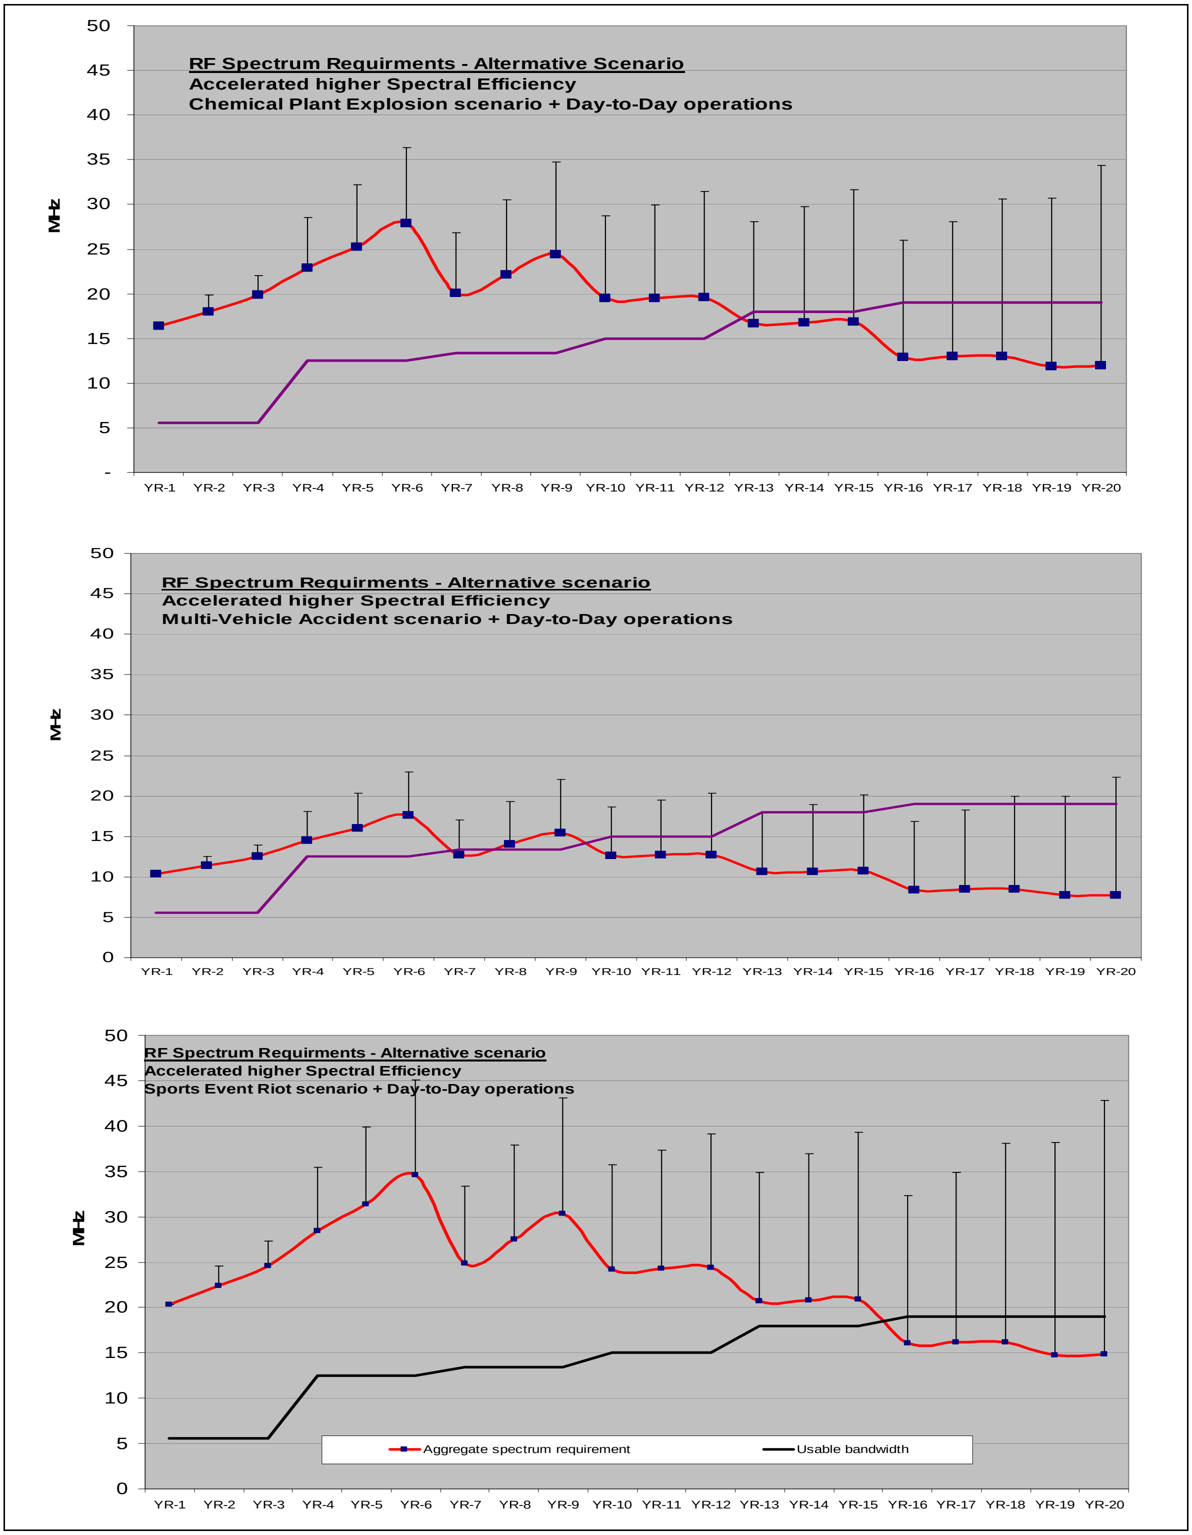

Figure 5.4: Aggregate (UL+DL) RF spectrum requirements considering accelerated improvement in SE.

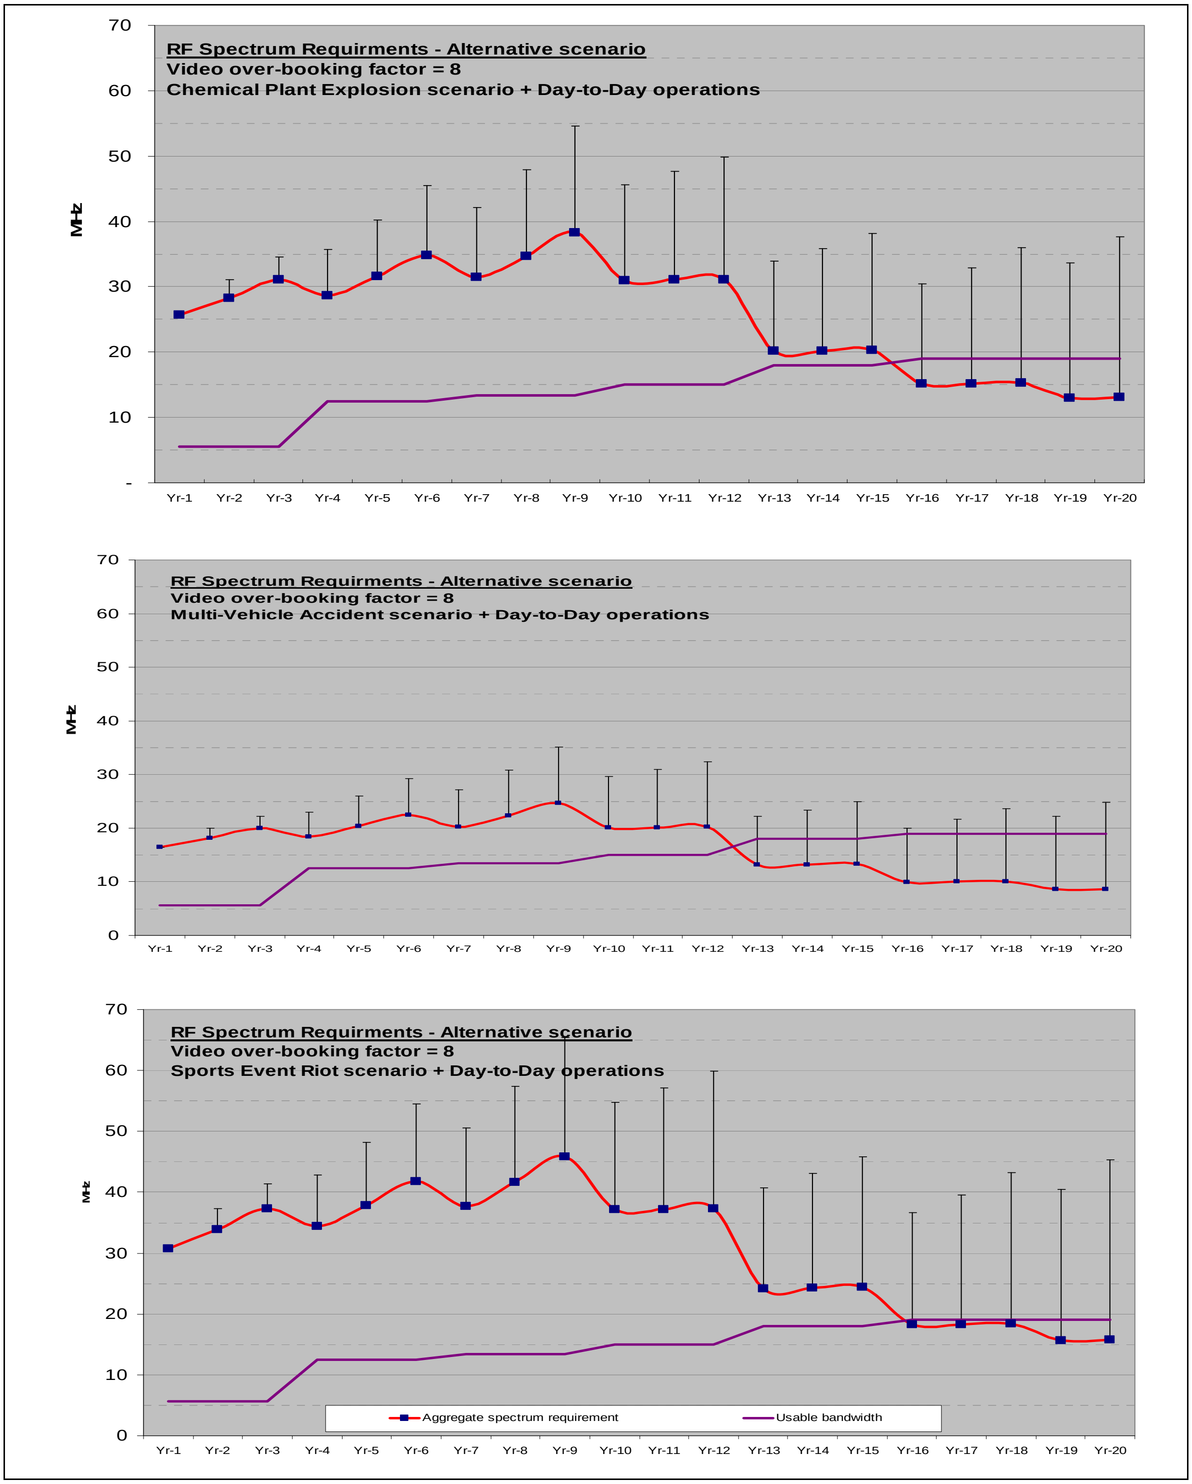

Figure 5.5: Aggregate (UL+DL) RF spectrum requirements considering aggressive OBF.

5.2.3 Level of compromise required to fit into 5+5MHz

Three parameters are simultaneously varied in order to determine how far public safety would have to back off from their requirements in order to fit into 5+5MHz of spectrum. The three parameters are:

- Video data rate
- Over-booking factor
- Spectral efficiency

In Figure 5.6(a,b,c) are graphs of RF Spectrum requirements which can be satisfied with 5+5MHz allocation. In order to fit into this profile, the following adaptations to the Model were made.

a) Video data rates were reduced by 50% compared to the values in the Model.

b) Over-booking factor was set to 20:1

c) Spectral efficiency was set to the un-derated values as in §5.2.1.

This means that in order for the data demands of the three incident case studies to be satisfied with 5+5MHz of the spectrum,

1. Video would not be usable to distinguish people, labels on chemical containers, or other similar level of detail.

2. The use of the network would have to be scaled back so that 1 in 20 users would be able to send or receive data simultaneously versus 1 in 4. One in 20 is the same OBF used by commercial carriers to dimension their networks for consumer-grade service.

3. New technology would need to be evaluated and implemented by public safety at the same pace as commercial carriers.

Item 3 above is based on optimistic expectations for technology roll-out. Items 1 and 2 would restrict the ability of first responders to make beneficial use of the network during emergencies. They would have to make significant compromises compared to how they intend to use a mobile broadband network if only 5+5MHz of spectrum would be available.

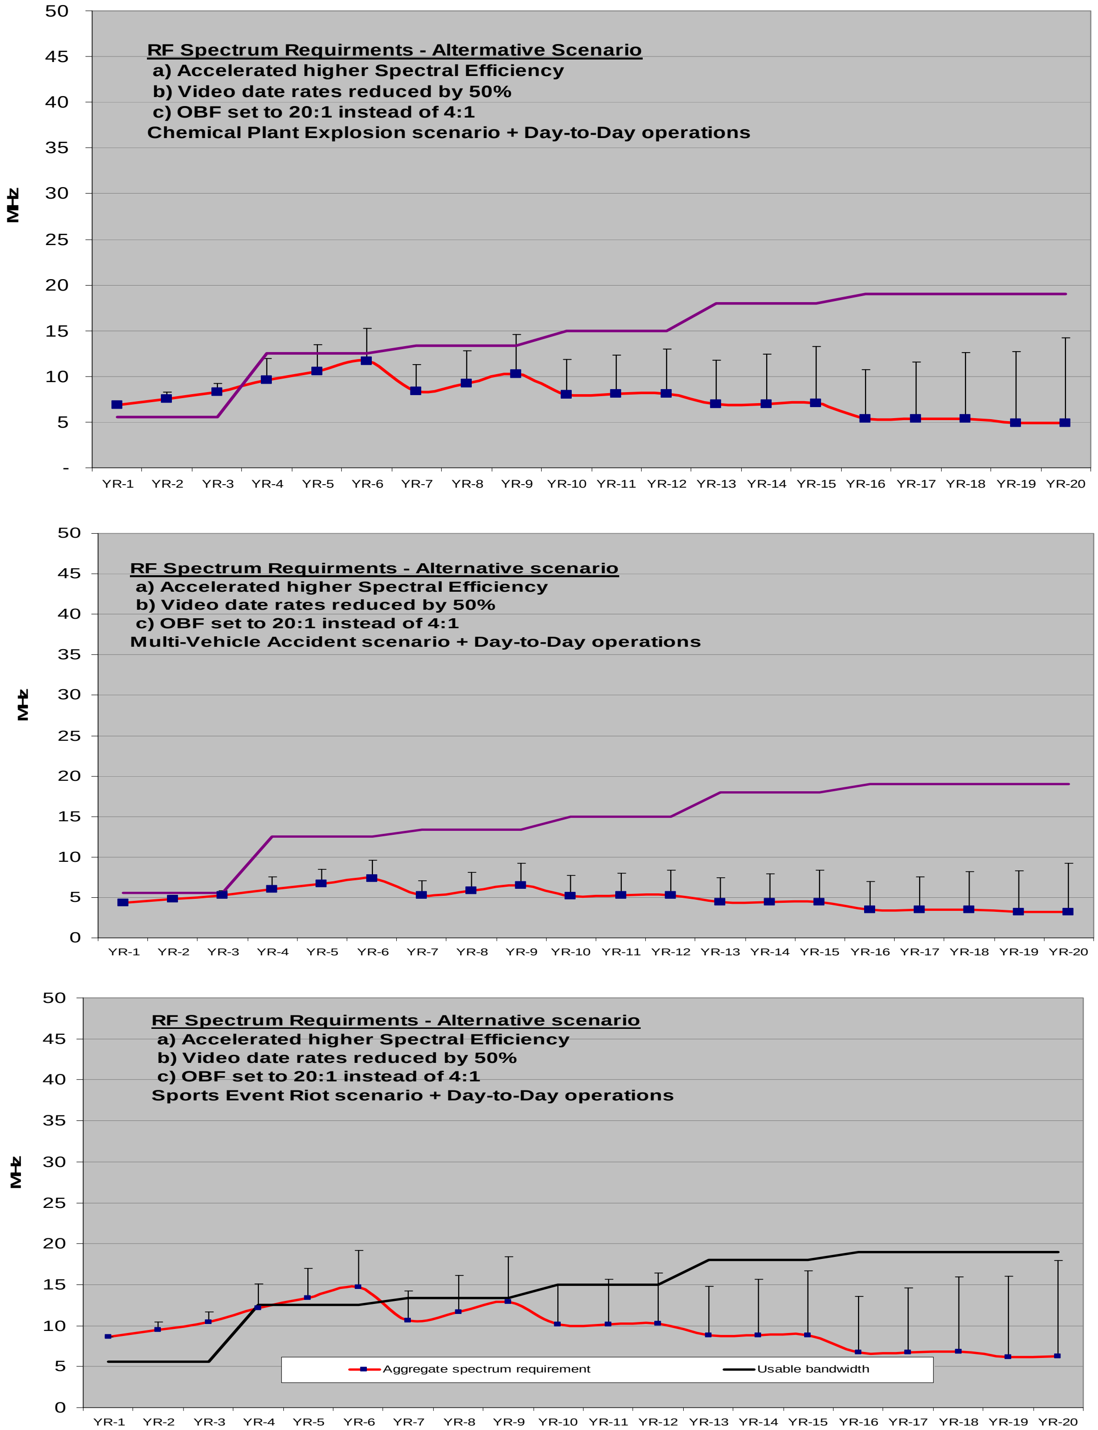

Figure 5.6: Level of compromise needed to fit spectrum requirements into 5+5MHz (UL+DL)

6 Conclusion

The question of how much bandwidth a mobile broadband network requires to meet the needs of public safety is answered by examining how the public safety community would use the technology and what throughput the technology offers.

This study followed a similar approach that others have taken to establish the anticipated usage. That is, to determine the data demand for incident scenarios of emergency events which are recurring in nature. Representatives from Canadian public safety stakeholders provided their views on how they anticipate using a mobile broadband network for three scenarios and how they would use the network in the course of their day-to-day operations.

The throughput requirements for each application that public safety could use were established based on empirical results from other studies and in consultation with the Communications Research Centre of Canada. The data demand profiles were determined from the anticipated usage and the applications data rates.

Correlating the data demand with the spectral efficiency of the mobile broadband network yields the required bandwidth. The analysis is performed for a 20-year horizon. LTE is the technology used in the study.

This study attempts to present a balanced perspective on demand and on capacity. It is unique in examining the effects of anticipated advances in technology to improve spectral efficiency over time and ways to manage high data-rate traffic such as video. The introduction of estimating error into the model is an innovative approach to quantify uncertainty of predicting future demand and capacity.

The key conclusions that are derived from this study are:

a) 10+10MHz is insufficient bandwidth to support the needs of public safety in the 10-15 year horizon.

b) Improvements in spectral efficiency will likely outpace public safety's demand for data and as a consequence, the requirement for bandwidth should begin to attenuate beyond YR10, which is the point when penetration of LTE devices in the public safety community is expected to saturate.

c) Despite the rapid pace of technical innovation, the ability to meet the needs of public safety with 10+10MHz of spectrum in a distant future, ie beyond 15 years, is not evident, but it is likely that 10+10MHz will not be sufficient at that time either..

In anticipation of being granted 20MHz of spectrum, and for the foreseeable future, congestion management will be an essential component of the mobile broadband network. The public safety community should develop policies and procedures, and make use of appropriate bandwidth management technology in order to avoid congestion-related issues during emergency situations.

It is not necessary to include here abstracts in both official languages unless the text is bilingual.)

In response to a request for technical advice by Public Safety Canada on behalf of national public safety stakeholders, the Centre for Security Science conducted a technical assessment of the 700 MHz spectrum requirements for broadband mobile data communications for public safety and security. The impetus to this assessment relates to the upcoming Industry Canada call for consultation SMSE-018-10. The goal was to determine how much spectrum is required to meet the needs of the public safety community for mobile broadband wireless data communications within a 20-year time frame. The data demand for recurring emergency situations was modeled through an interactive process with active participation from Canadian public safety stakeholders. In addition, the capabilities of LTE technology to support the data demands were also modeled. The results show that the amount of bandwidth required to satisfy the needs of public safety is greater than 20MHz in the near-to-mid term, and likely to also exceed 20MHz in the long term, despite advances in technology. This result is based on an analysis that applies relatively conservative estimates for the growth in demand for mobile data communications for public safety and security applications, and relatively aggressive estimates for the rate of technological improvement of spectrum efficiency projected into the future.

En réponse à une demande de conseils techniques faite par Sécurité publique Canada au nom des intervenants nationaux de la sécurité publique, le Centre des sciences pour la sécurité a effectué une évaluation technique des besoins de la fréquence de 700 MHz pour la transmission mobile à large bande de données destinée à la sécurité publique. C'est l'appel de consultation SMSE-018-10 que lancera bientôt Industrie Canada qui a motivé l'exécution de cette évaluation. L'objectif consistait à déterminer quelle part du spectre est requise pour répondre aux besoins du milieu de la sécurité publique pour la transmission mobile de données à large bande au cours des 20 prochaines années. La demande en données pour les situations d'urgences récurrentes a été modélisée à l'aide d'un processus interactif auquel les intervenants de la sécurité publique du Canada ont participé activement. Il y a de plus une modélisation des capacités de la technologie LTE pour répondre aux demandes de données. Les résultats démontrent que la part de la bande passante nécessaire pour répondre aux besoins de la sécurité publique est supérieure à 20 MHz à court et à moyen terme, et dépassera aussi probablement 20 MHz à long terme, et ce, malgré les progrès technologiques. Ce résultat repose sur une analyse ayant recours à des évaluations relativement prudentes de la croissance de la demande pour la transmission mobile de données à des fins de sécurité publique, ainsi qu'à des évaluations relativement ambitieuses du degré d'amélioration technologique de l'efficacité spectrale dans le futur.

14. KEYWORDS, DESCRIPTORS or IDENTIFIERS (Technically meaningful terms or short phrases that characterize a document and could be helpful in cataloguing the document. They should be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location may also be included. If possible keywords should be selected from a published thesaurus, e.g. Thesaurus of Engineering and Scientific Terms (TEST) and that thesaurus identified. If it is not possible to select indexing terms which are Unclassified, the classification of each should be indicated as with the title.)

700 MHz "D" Block

Public Safety Application Needs Assessment

January 2010

Commissioned by the Public Safety Foundation of America

Prepared by
Dr. Alan R. Shark, DPA
Executive Director
Public Technology Institute
Washington, DC

Table of Contents

Preface

In November 2009, the Public Technology Institute (PTI) was commissioned by the Public Safety Foundation of America to develop a briefing paper on critical application needs for public safety pertaining to the "D" block of the 700 MHz spectrum. PTI, a 501 (c) 3 nonprofit organization has been serving the technology needs of local governments for over 37 years and is one of the most respected organizations of its kind.

Special Thanks

PTI is indebted to Dr. Andrew Afflerbach, Ph.D., P.E., who is one of the most recognized engineers in the country when it comes to public safety system engineering. Dr. Afflerbach serves as the Director of Engineering for Columbia Telecommunications Corporation (CTC) and was most generous in sharing data from a recent CTC Report titled ***An Engineering Assessment of Select Technical Issues Raised in the Re-location of the D Block Spectrum*****,** which he authored, submitted in June 2008, prepared for the National Association of Telecommunication Officers & Advisors, National League of Cities, National Association of Counties, and the U.S. Conference of Mayors.

Also contributing to this paper is the City of Houston, the City of Phoenix and the endorsement of PTI's Public Safety Council.

About the Author

This paper was prepared and coordinated by Dr. Alan R. Shark, who serves as PTI's executive director. Dr. Shark was previously the CEO of the American Mobile Telecommunications Association (AMTA) for over 13 years and during his tenure served on the board of the Land Mobile Communications Council (LMCC). Dr. Shark is a fellow of the Radio Club of America and is a fellow of the National Academy of Public Administration. Dr. Shark is also on the faculty of Rutgers University for Public Affairs and Administration where he serves as an Assistant Professor.

About PTI

Public Technology Institute (PTI) is a national, not-for-profit member-supported organization based in Washington, D.C.

As the only technology organization created by and for cities and counties, PTI works with a core network of leading local government officials—the PTI membership—to identify opportunities for technology research, to share solutions and recognize member achievements, and to develop best practices that address the technology management, governance, and policy issues that impact local government.

Officials from PTI member governments participate in Councils and Forums that address specific technology areas. Through partnerships with industry, federal agencies and other governmental organizations, PTI shares the results of its activities and the expertise of its members with the broader audience of the more than 30,000 U.S. cities and counties.

About PSFA

The PSFA, a 501(c)(3) charitable organization, was established in January 2002 by the Association of Public-Safety Communications Officials International (APCO). The mission of PSFA is to engender cooperation among public and private groups to provide financial and technical support to the public safety communications community.

Funding for the PSFA has been provided by a variety of sources, including donations from corporations, APCO members and staff and the Wireless E-911: PSAP Readiness Fund, a non-profit organization established by Nextel Communications and dedicated to supporting the timely implementation of wireless E-911.

Executive Summary

When and how the 700 MHz D Block is ultimately allocated is critical to the deployment of a new and dynamic plethora of advanced high-tech public-safety applications. The 700 MHz band is exceptionally well suited for the new and demanding requirements of a new generation of video/data/voice devices. When compared to the 4.9 GHz public safety frequency allocation, the 700 MHZ band is far superior to that of the 4.9 GHz band because of the line-of-sight requirements and dramatically greater call density needs.

Public safety must not only plan for existing applications, it must also plan for the unanticipated crisis. Public safety has been plagued until now with inefficiencies of interoperable network operations, lack of quality and efficient broadband spectrum, and a lack of equipment, due largely to the uncertainties of the marketplace.

Public-safety-grade service demands special requirements that simply cannot be found in commercial systems. Commercial providers do not offer hardened network operations centers or hardened towers/repeaters, power surge capabilities, or quality-of-service outside of major Interstates and other high-density population centers.

This can be summed up with six factors as to why commercial grade networks are inadequate for public safety needs.

1. Coverage: Commercial networks are designed to be where the customers are, not necessarily where emergencies will occur. Not only are large land areas left un-served, but commercial systems are vulnerable to “dead zones” within service areas (e.g., inside buildings, in gaps between cell sites, areas blocked by terrain)

2. Reliability: Commercial networks generally lack the same degree of redundancy, power backups, hardened sites, and other controls necessary to limit outage times and the impact of outages.

3. Service restoration: A public-safety-controlled network will restore service much faster than a network controlled by a third party. The end user is not beholden to the network provider; it’s the other way around.

4. Capacity control: especially important during emergencies. Without absolute priority and control, critical communication could be sidelined by commercial service demands. With recent advances in commercial priority management, the system is still under the operational control of the commercial provider, and the technologies have as yet to be proven in times of an emergency.

5. Security: less of an issue than in the past, because of encryption, but still a concern as commercial systems are open to system-wide cyber attacks from its massive customer base.

6. Control: users of commercial networks have no say in future network upgrades, software changes, network management, etc, all of which have an impact on the service quality and cost.

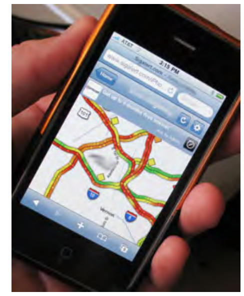
This Assessment highlights 13 out of over 25 distinct applications aimed to demonstrate the need for a larger universal broadband spectrum designated for public safety. A review of these applications should make it clear that these applications are not only real and necessary – they are bandwidth-intensive. According to what is referred to as Cooper's Law, "every 30 months the amount of information that can be transmitted over a given amount of radio spectrum doubles." (Marty Cooper, inventor of the hand-held cellular telephone).

This document also demonstrates rather conclusively that the 700 MHz D-Block and Public Safety Broadband License (PSBL) should be combined as a complete block, because of the mission-critical requirements and applications that have been highlighted.

Finally, this assessment briefly addresses the benefits to the public by way of improved safety and crime prevention, as well as more cost-saving efficiencies. It addresses the ability to better fight crime and terrorism, and the benefit of D block spectrum to the economy, as well as protecting our society against unknown threats.

Section One – Defining Application Needs Today

Critical Broadband Applications for Public Safety



The evolution of wireless communications continues at a maddening pace. In mid-2007 the iPhone was first launched - and lost in all the fanfare was that this phone was produced by a computer manufacturer and not a cell phone manufacturer. This device would change everything for consumers as every other manufacturer attempted to match or beat the iPhone. Today there are over 100,000 applications available, and there is no question that these devices have quietly morphed into powerful handheld computers that just happen to offer a decent phone as an "app."

The significance to the public safety universe is enormous, as often the first to a scene, be it a natural disaster, a car accident, a fire, or crime incident is the public. They are sending or downloading (or attempting to) photos and videos, and often as not, public safety systems are unable to fully take advantage of this new technology. However, as capable as some of these consumer devices are, there have been rising complaints regarding dropped calls, serious delays in text messages, and other network slowdowns caused by overtaxed or underbuilt networks in many key locations.

Consumer systems are quite different from public safety systems in that they are more market-oriented, whereas the public seems willing to accept inconsistent services in return for new and "cool" devices. In times of emergency, consumer devices become overwhelmed, and entire systems have been known to crash. Power outages also present a tremendous liability - consumer networks lack the adequate power back-ups that they may have once enjoyed with landline systems. Furthermore, the devices are not built to withstand the demanding public safety requirements, and thus the general public is fortunate to have a device lasting more than two years.

CIOs, CTOs, and public safety technologists were asked to articulate the many public safety applications that are either being deployed today or are being contemplated for the very near future. Of all the applications listed, everyone agreed that the Public Safety Broadband Spectrum (10 MHz) combined with the D-Block Spectrum (10 MHz) offers the most logical and necessary home for these new applications. The three reasons most often cited are:

1. 700 MHz has exceptionally good propagation characteristics when compared to alternative frequency bands.

2. The combined public safety broadband spectrum and the "D" block contain the desired bandwidth for important applications, especially video-related.

3. The size of the full block makes multi-usage systems possible and provides great economy of scale.

The following applications are either being deployed piecemeal or are being planned for the near future. Because public safety agencies lack a common spectrum for the newer technologies, the cost of equipment is far greater than it would be if the applications highlighted below were located in a single spectrum block, with appropriate rules and standards. Current systems that may operate on 700 MHz, 800 MHz, general pool, 800 MHz vacated spectrum, and NPSPAC are subject to a hodge-podge of situational-specific FCC rules, which make it very unlikely to be able to operate as a unified network.

Mobile Crime Scene Units

Most local enforcement agencies have mobile crime units of some kind; some in the form of buses, or vans. For mobile command applications to take better advantage of the latest technologies and communications systems, they will require greater bandwidth and spectrum to better integrate high-speed, high-definition video, data, and voice communications. Typically, the equipment used includes mobile, fingerprint reading and analysis, video crime scene analysis, and blood sample analysis, as well as perimeter protection and monitoring, and scene ID authentication.

Mobile Incident Command Centers

When natural disasters, major structural fires, hazmat incidents, hostage situations, or terrorism incidents strike, a mobile command center is required to coordinate and establish a mobile command system. The command center serves as the central hub for receiving and analyzing various voice communication paths, data monitoring and analysis, bio-monitoring, 3D building schematics and diagrams, GIS mapping, individual first-responder tracking, vehicle assets placement and tracking (AVL), incident ID authentication.

Automated License Plate Readers

This relatively new technology allows public safety officers to passively or actively scan vehicle license plates, either moving or parked. Data is retrieved from a specialized video camera and automatically sent to a database for immediate response. Such devices are particularly helpful with event management, "amber" or "silver" alerts, and seeking out individuals of interest.

Mobile Ticket Writer Systems

Mobile ticket writer systems allow for near-instant license look-up with full driver picture display, along with address, driving record, and any outstanding warrants. This type of system has been proven to dramatically increase productivity in ticket writing and leads to greater law enforcement personnel protection. Moreover, mobile ticket writing systems help ensure officer safety, as he or she would know instantaneously whether the subject is more than merely a traffic violator.

Streaming video and graphical display

Streaming video and graphic display requires its own category, as either separate or combined they require a huge amount of bandwidth – especially if offered as high-definition broadcast. Streaming video is required for mobile incident feeds and supplies critical visual information to various agencies and sites for improved coordination and multi-agency engagement.

Mobile Geospatial information systems

Leading city, county, and state agencies are increasingly relying on 3D geographical information databases where building schematics, wiring, ventilation systems, street conduits, underground structures, pipelines, subways, and other critical infrastructures are displayed. Mashed-up data is considered essential in being able to quickly respond to incidents and crises requiring immediate analysis and response.

Wireless Video Surveillance

Video surveillance offers public safety officials the ability to connect responding units within minutes and receive immediate feeds. The latest video technology provides for extreme low-light capture plus high-definition resolution. These must-have units also come with a large requirement for intensive bandwidth.

Multi-Modal Biometrics Monitoring Devices

Major cities and counties are looking to purchase multi-mode biometrics monitoring devices that are either fixed or mobile. Fixed units are designed to be deployed in or around major transportation hubs as well as in high-risk government buildings and structures, and landmarks. Mobile units are designed to be deployed at planned incidents such as parades, festivals, etc, and to warn of potential threat. Mobile units may also be deployed when an incident may be about to occur or has already occurred, and precise measurements are needed to ascertain site safety for first responders and the general public.

Fire Electronic Command Boards

New technology provides fire electronic command boards at the site where they are most needed and shared simultaneously with other command centers. A mobile command center is required to coordinate and establish a mobile command system when natural disasters, major structural fires, hazmat incidents, or terrorism incidents strike. The command board serves as the central hub for receiving and analyzing various voice communication paths, data monitoring and analysis, bio-monitoring, 3D building schematics and diagrams, GIS mapping, individual first-responder tracking, vehicle assets placement and tracking (AVL), and incident ID authentication.

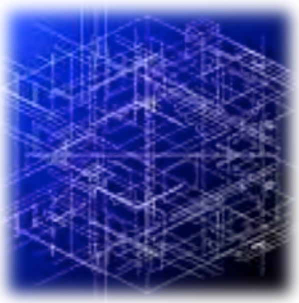
Emergency Medical Services AVL and Telemetry

Cities and counties have turned to AVL and telemetry systems to better coordinate their dispatch of first-responder units through improved tracking and system status management. ALS and BLS units can also broadcast key vital signs to medical experts in other locations, helping to better ensure life-saving care. With patient telemetry hospitals can be better prepared to offer life-saving measures before the patient arrives.

Facial Recognition/Video Analytics

With a growing population it is more important than ever before to deploy technologies that can utilize facial recognition to seek out persons of interest, or to simply permit passage of authorized first-responders to an incident or crime scene. Video analytics scans for visual anomalies, thus helping to track, guard, and monitor buildings, sites and events for suspicious behavior.

Floor plans, drawings, 3D graphical displays



Ideally, the benefits are obvious if every public safety vehicle has the capacity to view floor plans and have access to records, photos, and other 3D graphical displays. Each vehicle would be required to have a more powerful data terminal and screen capable of viewing high-definition video and audio. The irony here is that many believe the general public will have access to similar features with the next generation of broadband devices - slowed only by network capability and non-public-safety-grade equipment devices.

Patient tracking & video information systems

Emergency services and hospital and clinic facilities can benefit from deploying wireless systems that track patients at every stage of admittance, where staff can also view not only the tracking but also have the ability to access what procedures, meds, and other medical record information has been prescribed. As importantly, there is a critical need for incident commanders to track resources functioning at a common incident at any given instant.

Section Two: Efficiencies of 20 MHZ

Because public safety agencies lack a common spectrum for the newer technologies, the cost of equipment is far greater than it would be if the applications highlighted below were located in a single spectrum block, with appropriate rules and standards. Current systems that may operate on 700 MHz, 800 MHz, general pool, 800 MHz vacated spectrum, and NPSPAC are subject to a hodge-podge of situationally-specific FCC rules, which make it very unlikely to be able to operate as a unified network.

Of all the applications listed, there is overwhelming consensus among the public safety community the combination of "D" block and the public safety broadband block offers the most logical and necessary home for these new applications. The three reasons most often cited are:

1. 700 MHz has exceptionally good propagation characteristics when compared to alternative frequency bands.

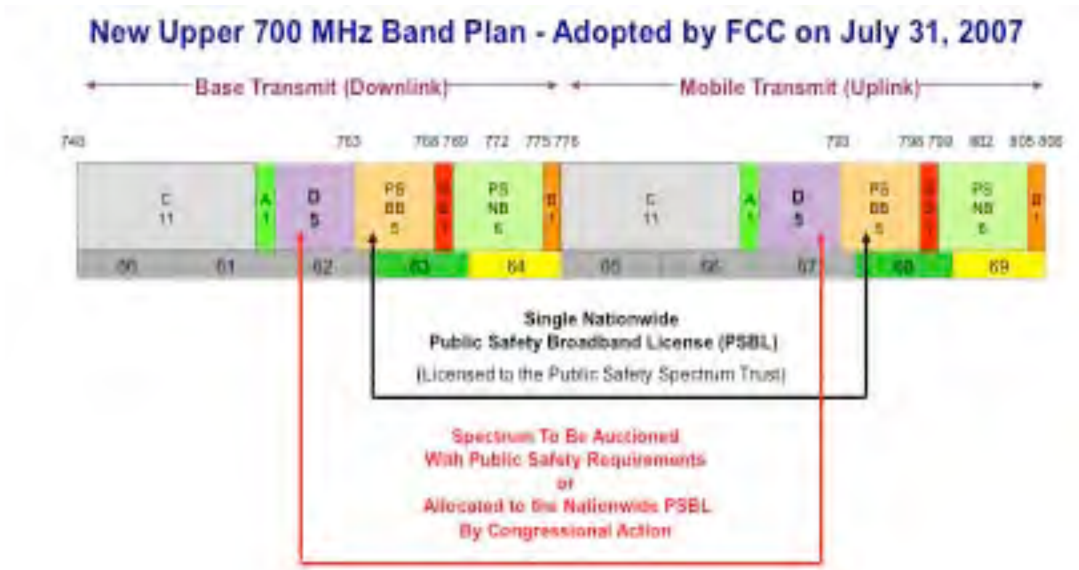
2. The additional "D" block will allow for the desired bandwidth to carry bandwidth intensive applications, especially video-related,

3. The additional "D" block will provide the capacity necessary during worst-case scenarios as an alternative to a more costly infrastructure.

With advances in technology, especially device processing power, and the need for quick reaction by emergency personnel near-total situational awareness at the resource unit level will be paramount. This is possible today through the utilization of cost-effective wireless technologies which make use of smart radio resources sharing techniques with appropriate quality of service (i.e. for user experience and priority mechanisms) and the right amount of spectrum. As demonstrated by a recent filing by New York City agencies to the FCC, given the kind of applications envisaged in the near to medium term and the number of first responders that are likely to intervene in a major event, the amount of broadband spectrum currently allocated to public safety will be insufficient to meet the needs of responders. In particular, the authors of the NYC Report note "It is clear from our analysis that in scenarios where 20 MHz of spectrum is available to public safety the system will be "stressed" during periods where important characteristics of a network need to exist above and beyond what is available commercially".

Furthermore, while not reflected in the previous section on foreseen applications, it is becoming apparent that in the years to come there may be a desire to provide more spectrally-efficient voice services either as an alternative to current LMR or as a backup to the latter; more so if there is a desire by first responders to carry a single single-mode (rather than multi-mode) device. As reflected in the NYC analysis, the provision of such voice services would stress a broadband system further unless additional bandwidth is available.

The size of the full block makes multi-usage systems possible and provides great economy of scale. Given some the frustrations stemming from significant delays in broadcast migration and a failed auction for the D Block, some have concluded that new methods should be devised to allocate spectrum. However, based on numerous reviews of public safety communications planning, a single block is not only economically necessary, it is required for sound spectrum management implementation.



PTI, as well as most authoritative experts in spectrum management, believes that keeping the D Block and the public safety broadband block together is advisable from a technical standpoint. That spectrum combination should enable a more efficient use of spectrum and other technical resources.

The following is taken verbatim, with permission, from ***An Engineering Assessment of Select Technical Issues Raised in the Re-location of the D Block Spectrum*** authored by Dr. Andrew Afflerbach, Ph.D. P.E., of Columbia Telecommunications Corporation (CTC) submitted in June 2008, prepared for the National Association of Telecommunication Officers & Advisors, National League of Cities, National Association of Counties, and the U.S. Conference of Mayors. In this engineering assessment, Dr. Afflerbach states several reasons why this is a technical benefit to keep the D Block intact:

a. It’s a significant advantage to *commercial* D Block customers—they will be receiving services from a public-safety-grade network that is clearly superior to other commercial networks, because it was designed to meet first-responder needs.

b. Operating a single network in the spectrum will enable a greater body of users to benefit from the antennas, radios, towers, and backhaul systems that will need to be built. If there were separate commercial and public safety networks in the 22 MHz of spectrum, the infrastructure would cost twice as much to operate. Efficiency arises from the sharing, by commercial and public safety networks, of a single platform with a single set of antenna structures, base stations, backhaul, management systems, and RF designers.

If a service provider must build a new network to activate a separate channel band, the cost of the activation may be millions or tens of millions of dollars in a single metropolitan area. Carrier broadband wireless architectures may require base stations every 1.5 kilometers. Individual base station costs vary widely, depending on environment and the needs of a particular area, but are on the order of magnitude of \$100,000, plus ongoing lease fees. Backhaul costs are significant, with \$50,000 to \$150,000 required to build a mile of fiber optic cable, or thousands or tens of thousands of dollars per month required to lease comparable capacity from a service provider.

c. A joint build-out will result in less impact to the public rights-of-way, because fewer towers, antennas, microwave infrastructure, and/or fiber infrastructure would need to be constructed.

d. Larger spectrum blocks enable operation with large channel bandwidths and high power—making it possible for devices to attain a given speed with fewer towers, each serving a larger area. This type of operation is particularly suitable for blanketing a larger geographic area, as would be necessary to cover rural areas.

e. Larger blocks of spectrum increase the flexibility for serving areas near international borders. King County, WA, for example, has noted the extreme difficulty of operating a wireless network in a major U.S. metropolitan area (Seattle) that adjoins a major Canadian metropolitan area (Vancouver)—and in which each of these networks must share spectrum with the other.

f. If, instead, two adjacent, non-coordinated networks operate in the aggregate 22 MHz, the spectrum allocation will require a guard band between the two allocations, which are currently not separated by a guard band, on the assumption that the two blocks will be operated as a whole. Adding a guard band will entail decreasing the allocation of spectrum to the D Block. A greater loss of spectrum use will result, because of the need for guard bands and mitigation of RF interference among the many individual providers/bands.

Section Three: The Value to Public Safety and the Citizens Served

This assessment would not be complete without mentioning the benefits to the public by way of improved safety and crime prevention, as well as more cost-saving efficiencies. In light of the Oklahoma City bombing and the World Trade Center disasters the public is demanding better protection and security everywhere. During the past several years the public safety communities have rallied together and have responded to citizen needs in no less than three ways.

1. First, the public safety community has deployed new video surveillance systems, bio-monitoring devices, and improved communications systems aimed at not only improving internal communications but to address citizen needs for information in a direct and timely manner.

2. Second, many of the applications mentioned in this assessment address the need for greater speed in responding to disasters – be it man-made or natural.

3. Third, a majority of the applications highlighted are designed to actually save both lives and monies. Wireless applications can reduce the need for more personnel and improve upon efficiencies of scale through shared networks, realizing efficiencies through more intelligent deployments and improved field operations.

While all these efficiencies and benefits are being realized, the public safety community remains committed to retaining the good will they enjoy through continued vigilance in adopting new technologies that protect our citizens against known and unknown threats.

Appendix B – Letters of Support

United States Senate
COMMITTEE ON COMMERCE, SCIENCE
AND TRANSPORTATION
WASHINGTON, DC 20510-6125
Web site: http://commerce.senate.gov

August 26, 2011

The Honorable Julius Genachowski
Chairman
Federal Communications Commission
445 12th Street SW
Washington, DC 20554

Dear Chairman Genachowski,

This week's 5.8 magnitude earthquake on the East Coast was just the most recent example in which many Americans were unable to use a communications network they rely upon for their safety and security. Residents and first responders along the East Coast may again face this problem as they brace for the predicted landfall of Hurricane Irene this weekend. As we are now in the midst of hurricane season, the Federal Communications Commission (FCC) should work to make sure that our nation's communications infrastructure is up to the task. Americans should expect that they can reach their loved ones during an emergency. But our commercial networks are asked to do much more. Because first responders still do not have a nationwide wireless broadband network of their own, they must rely on these same commercial networks if they hope to access any mobile data services, such as text messaging and emails.

Despite being six years from the devastation caused by Hurricane Katrina and ten years from the tragic events of 9/11, we still do not have an interoperable wireless broadband network for public safety. We must not allow any more potentially life-threatening disasters to occur before our nation's first responders get the interoperable public safety communications system they need to keep us safe. And, as the communications troubles following the earthquake reminded us, we cannot require public safety to rely exclusively on commercial networks for their mission-critical, advanced wireless communications needs.

While many people were frustrated by the overloaded commercial networks this week, the stakes of such problems can become a matter of life or death for first responders. Some of the brave men and women who risk their lives every day to protect the rest of us experienced the same inability to communicate following this week's earthquake. In fact, the threat was so serious that the Federal Emergency Management Agency asked members of the public to refrain from making calls on their mobile phones for a period of several hours following the quake so that emergency officials could continue to receive and respond to urgent communications. Many first responders were forced to rely on their voice-only land mobile radios because commercial networks are not reliable for mission-critical services during emergencies. Unfortunately, until we can provide public safety with the spectrum and funding they need to build a dedicated nationwide interoperable wireless broadband network, our first responders and the Americans who depend on them will be at the mercy of increasingly congested networks for their advanced wireless communications needs.

The commercial network infrastructure has greatly improved in the past decade, but the congestion following Tuesday's earthquake clearly demonstrates the need for more commercial spectrum. In recent years, wireless congestion has sometimes been a problem for consumers even in the best of times, let alone during the worst of times. Indeed, network problems like we saw this week may become even more frequent if the government does not act quickly to make more spectrum available for advanced wireless services.

As you know, we are working to address these problems. Earlier this year, we introduced S. 911, the Public Safety Spectrum and Wireless Innovation Act. This bi-partisan measure has the support of our nation's first responders, as well as President Obama and our nation's Governors and mayors. The bill would give our nation's first responders the dedicated spectrum and funding necessary to deploy an interoperable wireless broadband network for public safety use. It would also pump a huge amount of spectrum into the commercial wireless ecosystem. Our bill addresses one of the last outstanding recommendations of the 9/11 Commission, promises to save lives, would create hundreds of thousands of jobs without costing taxpayers a dime, and provides billions for deficit reduction. We will continue to press our colleagues in Congress to approve this measure as soon as possible.

We understand that the FCC is conducting a thorough assessment of the outages associated with this week's earthquake to determine what steps may be appropriate to improve communications services during emergencies. We urge you to complete that analysis as quickly as possible.

Sincerely,

Jay Rockefeller

John D. Rockefeller, IV
Chairman
Senate Committee on Commerce, Science, and Transportation

Kay Bailey Hutchison

Kay Bailey Hutchison
Ranking Member
Senate Committee on Commerce, Science, and Transportation

BIPARTISAN POLICY CENTER

June 7, 2011

The Honorable Jay Rockefeller
Chairman

Science, and Transportation
253 Russell Senate Office Bldg.
Washington, DC 20510

The Honorable Kay Bailey Hutchison
Ranking Member
U.S. Senate Committee on Commerce,
Science, and Transportation
253 Russell Senate Office Bldg.
Washington, DC 20510

Dear Chairman Rockefeller and Ranking Member Hutchison:

The inability of first responders to communicate with each other was a critical failure on September 11, 2001. Incompatible and inadequate communications led to needless loss of life. To remedy this failure, the 9/11 Commission recommended legislation to provide for the expedited and increased assignment of radio spectrum for public safety purposes.

We commend the Senate Commerce Committee for marking up the SPECTRUM Act (S. 911), which will allocate an additional 10 MHz of radio spectrum—the "D block"—to public safety. Using this spectrum, public safety agencies will be able to build a nationwide interoperable broadband network, allowing diverse agencies to communicate with each other, and supporting mission critical voice, video, text, and other data transmissions.

This legislation takes an important step forward in improving interoperability for first responders. We note, however, that first responders utilizing the D block public safety network may not be able to communicate on other networks should the D block go down in an emergency. Therefore, we urge the committee to examine how this type of interoperability can be achieved through this or other legislation.

We support the expeditious allocation of the D block spectrum to public safety. Congress must not approach this urgent matter at a leisurely pace, because quite literally lives are at stake.

Thank you for your vital efforts in this area.

Sincerely,

Tom Kean
9/11 Commission Chairman
Co-Chair, National Security
Preparedness Group

Alcatel-Lucent position statement on proposed D Block auction

Over the past few years, Congress has taken important first steps to address the vital issue of public safety interoperability by expediting the increased assignment of radio spectrum for our nation's first responders. There is clearly no debate on the fact that the public safety community must have effective, reliable and interoperable communications, especially during times of national emergency, but also on a day-to-day basis whenever a police officer, fire fighter or other public safety must respond quickly and efficiently. Unfortunately, although Congress provided 24 MHz in the 700 MHz band for public safety narrowband and broadband use to be administered by the Federal Communications Commission, this effort has fallen woefully short in terms of moving interoperability issue forward.

Once again, the FCC is planning to address this issue by the disposition of the D Block via auction, a process that failed miserably when previously implement. Public safety officials, service providers and infrastructure vendors agree that a more effective method would be to allocate the D Block directly to public safety organizations in order to create a national broadband network that would meet the critical needs of first responders.

Alcatel-Lucent has been at the forefront in supporting the creation of a national interoperable public safety broadband network. We strongly oppose another FCC auction and vigorously support the Congress directly reallocating the D Block to public safety.

Moreover, we support federal funding of a public safety nationwide interoperable broadband network for our nation's first responders. Congress' support in the American Recovery and Reinvestment Act of 2009 to partially address potential funding for public safety networks via the Broadband Technology Opportunities Program ("BTOP") directed by the National Telecommunications and Information Administration is a crucial first step, but more needs to be done.[1] Additional federal grant opportunities focused on 700 MHz broadband first responder networks will facilitate the rapid deployment of these networks across the United States. But there is a need to get started today and BTOP funding would allow those jurisdictions that have filed FCC waiver requests to begin deployment of public safety broadband networks this year. Fourteen jurisdictions across the country have petitioned the Commission via waiver to early deploy under the FCC's rules an interoperable 700 MHz public safety broadband network, as was envisioned by the 9/11 Commission. These jurisdictions include the States of New York and Hawaii, large and small cities New York and Chesapeake, Virginia and larger regions, such as the San Francisco Bay Area and the Los Angeles Region.

We encourage Congress to take action that would ensure the FCC grants waiver requests that not only meet the Commission's rules, but also result in networks that are clearly in the public interest and that result in saved lives.

July 21, 2010

AT&T Statement on Sen. Rockefeller and Public Safety Legislation

Background – Senator John D. (Jay) Rockefeller IV, Chairman of the U.S. Senate Commerce, Science, and Transportation Committee, today announced his intent to introduce the Public Safety Spectrum and Wireless Innovation Act (S. 3756). The following statement may be attributed to Tim McKone, AT&T Executive Vice President-Federal Relations.

"AT&T applauds Senator Rockefeller's commitment to introduce the Public Safety Spectrum and Wireless Innovation Act. Spectrum is a scarce and valuable national commodity, but we are encouraged by Senator Rockefeller's action today that public safety will have sufficient resources to support a nationwide wireless broadband network. It is vital that our first responders have access to a robust, interoperable network to ensure the public's safety and preserve national security.

"By authorizing the FCC to conduct incentive auctions, the Act will create a mechanism that will not only unleash new spectrum allocations for the wireless networks of the future, but will provide critical funding support. This Act is poised to be a tremendous win for public safety and for wireless consumers."

Committee on Commerce, Science, and Transportation
United States Senate
Washington, D.C. 20510

Dear Chairman Rockefeller, Chairman Kerry, Ranking Member Hutchison and Ranking Member Ensign:

As national organizations representing state and local government officials, we request that you oppose a commercial auction of the 700 MHz D block and support legislation to reallocate the D block of spectrum to public safety. The utilization of broadband technology is crucial to the future of public safety and will enhance the ability to save lives by quickly sharing information with first responders, public institutions and private citizens. Allocating the D block directly to public safety is the only way to ensure a robust, modern and reliable nationwide interoperable network.

For years, state and local first responders have sought to build a national interoperable communications network that allows real-time information sharing through high speed video and data. This requires an appropriate, dedicated band of spectrum that can accommodate the everyday needs of firefighters, police officers and emergency medical personnel, as well as provide excess capacity during times of emergency. The 700 MHz D block finally provides this opportunity. While the Federal Communications Commission's National Broadband Plan proposes to provide public safety roaming and priority access on other commercial 700 MHz networks for a fee, this proposal relies on untested technologies and new regulations that cannot ensure reliable and resilient communications capabilities to meet stringent public safety needs.

We urge you to support reallocation of the D block to ensure this one time opportunity to develop a nationwide interoperable network for public safety is not lost.

Senator Richard Blumenthal
30 Lewis Street STE 101
Hartford, CT. 06103

Dear Senator Blumenthal,

As Chief of the Bridgeport Police Department, I am writing to advise you of my strong support of the ***Public Safety Spectrum and Wireless Innovation Act* (S. 28), sponsored by Sen. Jay Rockefeller (D-WV)** The legislation will allocate D-Block spectrum to public safety for the development of a nationwide interoperable public safety broadband network and designate significant funds to build out and operate the nationwide network.

Law enforcement and public safety must have a minimum of 20 MHz of broadband spectrum to meet current and future needs and must have access to new technologies to perform increasingly complex duties. These technologies must have adequate and dedicated spectrum that is managed and controlled by public safety to ensure that they will be more secure and reliable than commercial systems. The D-Block allocation and funding is essential if we are to meet the critical needs of our nation's law enforcement and public safety community.

I am proud to support **S. 28**, and I urge you to support our efforts as well.

Sincerely,

Chief Joseph L. Gaudett, Jr.
Chief of Police, Bridgeport, CT.

Senator
I appreciate your attention to this matter.

Re: Support for D Block Spectrum to Public Safety Community

Dear Congressman Conyers:

The Conference of Western Wayne is a bi-partisan and regional organization of eighteen Western Wayne County municipalities. Our Board of chief elected officials speaks to you unanimously and on behalf of their 700,000 residents.

For the safety of our citizens and to protect critical businesses in the Southeast Michigan area, we urge you to work with your colleagues to support the legislation that will allocate the D Block Spectrum to the public safety community.

We believe that our State, local and Tribal first responders, including law enforcement, fire, medical and emergency professionals, must have access to the most modern and reliable wireless broadband technologies. The additional 10 MHz of spectrum that the D Block provides would be leveraged with 10 MHz of adjacent spectrum that the public safety community has at its disposal in order to create a 20 MHz network that is essential to supporting a wide range of public safety, government, critical infrastructure and consumer needs for voice, video and data services.

Your support for legislation that would allocate D Block for public safety would send a clear message to your colleagues and to members of the Federal Communications Commission. The D block spectrum wireless designation for public safety is needed as an essential element of national security.

We look forward to receiving your commitment of support for D Block legislation. The CWW Board along with Michigan's first, second and situational responders are confident in your leadership.

Sincerely,

Marsha Bianconi

SBE COUNCIL
Small Business & Entrepreneurship Council

D Block Support Statement

"The Small Business and Entrepreneurship Council (SBEC) supports fully allocating 20 MHz of contiguous spectrum from the 700MHz D Block to public safety so that police, fire, and emergency personnel possess the dedicated spectrum necessary to build and operate a nationwide interoperable wireless broadband network. Public safety's communications requirements are vastly different than those of commercial users, such as needing a state of the art network capable of handling peak loads and providing high bandwidth access to thousands of users simultaneously. The only way such a network is possible is with spectrum dedicated exclusively for public safety use."

The Honorable Nancy Pelosi
Minority Leader
U.S. House of Representatives
Washington, D.C. 20515

Dear Majority Leader Reid, Senator McConnell, Speaker Boehner, and Representative Pelosi

On behalf of the nation's governors, we are writing to urge your support in passing S. 911, *the Public Safety Spectrum and Wireless Innovation Act*, before the 10th anniversary of the terrorist attacks of September 11, 2001. This bipartisan legislation would protect critical public safety communications now and into the future by providing the necessary spectrum, governance and funding to make the nation's first interoperable public safety network a reality.

On the morning of September 11, 2001, the nation watched as thousands lost their lives in the tragic and unprecedented terrorist attacks on the nation's soil. On that day, firefighters, police officers and emergency medical personnel immediately responded to assist the injured and prevent further loss of life. Unfortunately, many of these heroic men and women lost their lives due to the inability to communicate with other first responders on site. Since that time, governors have worked with public safety officials and the federal government to strengthen first responder communications. One important step toward this national goal is the development of a nationwide interoperable *broadband* network for public safety.

As we begin developing the nationwide network, we have a unique opportunity to dramatically transform how first responders communicate and how we deliver life-saving and life-sustaining services to our citizens. Similar to the demand for commercial spectrum, public safety also requires additional spectrum to cost-effectively build and maintain a network. This can best be achieved by reallocating the 10 MHz of D block spectrum to public safety.

Reallocating the D block will meet the critical needs of first responders and allow state and local governments to establish new and innovative partnerships to improve the delivery of government services and provide funding to maintain these systems over time. Combining the D block with the existing public safety broadband spectrum will also help reduce costs by allowing the future consolidation of voice and data systems. On the other hand, the failure to reallocate the D block will preclude public safety entities, and the state and local governments that support them, the opportunity to pursue these cost reductions and programmatic advantages.

Despite the nation's troubling economic conditions, our law enforcement, firefighters and emergency medical personnel must continue to save lives and protect us from harm. S. 911 recognizes the imperative of providing public safety with the capabilities they require while balancing important financial considerations. Not only does the legislation reallocate the D block to provide sufficient contiguous spectrum, but it pays for this reallocation while also providing funding to develop the network and reduce the deficit by billions of dollars.

We thank you for your support and hope you share our desire to pass this important legislation as quickly as possible.

Sincerely,

Janice K. Brewer

Governor Janice K. Brewer
Co-Chair
Special Committee on Homeland Security and Public Safety

Governor Martin O'Malley
Co-Chair
Special Committee on Homeland Security and Public Safety

911

Executive Director
Mark A. Jongekrijg
Deputy Director

April 21, 2011

The Honorable Fred Upton
Chairman, House Energy and Commerce Committee
United States House of Representatives
Washington, DC 20515

Dear Representative Upton

I urge you work with your colleagues in the House Energy and Commerce Committee to quickly take up legislation that will allocate the D Block spectrum to the public safety community and will provide the funding necessary to build out a nationwide interoperable and mission critical broadband network.

I feel strongly that our State, local and Tribal first responders, including law enforcement, fire, medical and emergency professionals, must have access to the most modern and reliable wireless broadband technologies to communicate with each other across various agencies and jurisdictions. The additional 10 MHz of spectrum that the D Block provides would be leveraged with 10 MHz of adjacent spectrum that the public safety community has at its disposal in order to create a 20 MHz network that is essential to supporting a wide range of public safety, government, critical infrastructure and consumer needs for voice, video and data services.

Your support for legislation that addresses this will allocate D Block to public safety will ultimately send a clear message to your colleagues in Congress, at the Federal Communications Commission and in the current Administration that wireless broadband for first, second and situational responders is a top national priority.

I look forward to receiving your commitment as the Chairman of the House Energy and Commerce Committee to make this a top priority for your Committee. Michigan's first, second and situational responders are looking to you to lead the way on behalf of the entire public safety community.

Sincerely,

Timothy F. Smith
Executive Director

Patrick McGinnis
Policy Board Chairman

September 21, 2010

The Honorable John D. Rockefeller
Chairman
Committee on Commerce, Science and Transportation
United States Senate
Washington, D.C. 20510

Dear Chairman Rockefeller:

The universal availability of secure, reliable, priority access and public safety grade broadband communications is critical to the advancement of emergency medical care for patients in the United States. The best way to assure this availability is to allocate the 700 MHz D block to public safety for use in conjunction with the 700 MHz broadband spectrum licensed to the national public safety broadband license holder, to fund network development, and to coordinate both sets of spectrum through that license holder and its public safety representative board. We strongly endorse your legislation, S. 3756 - the Public Safety Spectrum and Wireless Innovation Act of 2010, and hope that it will become the vehicle to accomplish this.

As national organizations representing emergency medical service (EMS) provider agencies, professionals, and EMS system and service officials, we wish to emphasize that the potential provided by new field EMS diagnostic and treatment technology is impeded by the limitations of the narrowband communications systems we have used, basically without change, since the early 1970's. We believe that EMS may well become one of the biggest users of public safety broadband to bring lifesaving capabilities to our patients. We encourage your staff to work with leaders of the Public Safety Alliance and Public Safety Spectrum Trust to tailor this legislation to best meet these needs.

We offer you our support in making S.3756 a success for the Nation.

Sincerely,

Office of the Governor

February 17, 2011

Senator Jay Rockefeller
31 Hart Senate Office Building
Washington, DC
20510

Senator Kay Bailey Hutchinson
284 Russell Senate Office Building
Washington, DC
20510

Dear Senators Rockefeller and Hutchison,

I want to take this opportunity to support the reallocation of the 700 MHz D block spectrum for public safety. This would address the frequency inadequacies currently inhibiting the build-out and operation of public safety 700 MHz radio systems.

Currently, Louisiana has one of the largest 700 MHz statewide radio systems in existence. Given the name Louisiana Wireless Information Network (LWIN), this system is comprised of over 100 tower sites that provide almost 95% statewide coverage available to all local, tribal, state, and federal partners. Supporting over 60,000 users, the system provides communication capabilities that supported over 95 million "push-to-talk" conversations in Louisiana during the 2010 calendar year. This achievement has been made possible by dedicating hundreds of millions of dollars in local, state, and federal monies over the past five years.

Just one example of LWIN's advanced capabilities can be seen in the system's performance during the BP Oil Spill in the Gulf of Mexico. Coordinating with sister-states of Mississippi and Texas as well as the city of Orange Beach, Alabama, the State of Louisiana managed the creation of the Gulf Wireless Information Network (GulfWIN). GulfWIN created a series of patches and interstate connections between the different radio systems to give the responders coverage from Corpus Christi, Texas, to Pensacola, Florida. GulfWIN allowed the myriad jurisdictions, functional areas, and geographically dispersed responders the ability to communicate using a standard, shared resource. As with any emergency response, the judicial use of and conservation of scarce resources has a major impact on the ability of public safety responders to function. GulfWIN not only provided an interoperable communication path for easier coordination, but it also alleviated the need to duplicate efforts if each local, state, and federal partner had been required to establish their own radio system.

While this is just one example of LWIN's success, there are still many hurdles that must be overcome. Frequency allocation is one of the most critical issues that currently impacts the establishment and expansion of statewide radio systems. This is especially important in Louisiana as we look to add additional capacity to LWIN and establish data interoperability for Louisiana's first responders. As with any resource, there is a limit to the amount of frequencies that are available to public safety. With the ever expanding demand for first responders to be able to handle any threat, be it natural or man-made, the need for interoperable communications between the different levels of government becomes ever more

(225) 342-7015 ✤ Fax (225) 342-7099 ✤ www.gov.state.la.us

crucial. In conjunction with this need for interoperable communications, there is an increasing need for additional spectrum.

LWIN and GulfWIN are considered examples of excellence for the rest of the Nation. GulfWIN can also be held as a model for the implementation of a national public safety radio system. Therefore, I support and encourage the allocation of the 700 MHz D block spectrum to be reallocated to public safety.

Sincerely,

Bobby Jindal
Governor

Office of the Governor

June 10, 2011

The Honorable Harry Reid
U.S. Senate Majority Leader
522 Hart Senate Office Building
Washington, DC 20510

Dear Majority Leader Reid:

I am writing to ask your support in reallocating the D-block of spectrum to public safety which will meet the emergency communications needs of our first responders.

For years, state and local first responders in Nevada and around the country have sought to build a national interoperable communications network that allows real-time information sharing through high speed video and data. This requires a dedicated band of spectrum that can accommodate both the everyday needs of firefighters, police officers and emergency medical personnel, as well as provide excess capacity during times of emergency. The D-block finally provides this opportunity.

As you know, the Federal Communications Commission (FCC) plans to auction the D-Block for commercial purposes. In its National Broadband Plan, the FCC proposes to meet public safety spectrum needs by providing roaming and priority access on other commercial 700 MHz networks for a fee. This proposal is insufficient because it will not meet stringent public safety requirements necessary to protect lives and will increase the costs of achieving and maintaining operable and interoperable emergency communications for years to come.

By reallocating the D-Block to public safety, you have the opportunity not only to ensure that our police officers and firefighters have access to advanced technologies the rest of us take for granted, but also to ensure we avoid the mistakes of the past that have made public safety communications systems complex and costly. The location of the D-Block offers a unique opportunity to ensure first responders not only have access to sufficient spectrum, but will also allow state and local governments to take advantage of efficiencies of scale and reduce the costs of such systems that must be maintained by taxpayers over time.

The bipartisan Spectrum Act, S.911, has been introduced in the Senate to reallocate the D-Block to public safety. I urge you to support this legislation and to ensure this one time opportunity to develop a cost-effective nationwide interoperable network for first responders in Nevada is not lost.

Sincere regards,

BRIAN SANDOVAL
Governor

May 5, 2010

The Honorable Julius Genachowski
Chairman
Federal Communications Commission
445 12th Street SW
Washington, DC 20554

Subject: Public Safety Need for 700 MHz and D Block

Dear Chairman Genachowski:

The undersigned have diverse backgrounds in business and the public sector and we share the privilege of having been early leaders at the U.S. Department of Homeland Security. We are acutely aware of the vital need that America's first responders have today for substantially expanded access to broadband spectrum and we write to request your support for these spectrum needs.

One of the most solvable problems from such nightmares as the terrorist attacks of 9/11 and landfall of Hurricane Katrina remains unsolved. That problem is the guaranteed availability of adequate interoperable public safety communications when such catastrophic disasters occur. A huge step can be taken toward ensuring such access by allocating the 10 MHz of the 700 MHz spectrum, known as the D Block, to public safety. We strongly support the petition of New York City and numerous other first responder organizations that "a single wireless broadband network combining the D Block and the adjacent public safety 700 MHz spectrum is the only logical choice to satisfy public safety broadband wireless spectrum requirements."[1]

The nation has rightfully insisted that our first responders and other key municipal services operate smarter. A host of technologies to support daily operations and surge operations would use this spectrum. Excess capacity during non-surge periods can be efficiently leased to commercial users. Allocating the D Block to public safety will dramatically improve emergency *preparedness*, allowing first responders to *perform* better. It would also incentivize device manufacturers to offer more sophisticated, integrated single-device solutions to manage daily needs and surge needs for mission-critical voice and data transmission – and do so at reasonable prices. It will similarly encourage rapid development of new voice, data and video applications that improve safety and security.

Precisely in the periods of utmost need, when all communications demand surges, our first responder community needs to have guaranteed access to the broadband spectrum that will support its growing need for increased throughput and interoperability. This is indeed a fateful public policy decision.

---

[1] White Paper co-authored by the New York City Police Department, New York City Fire Department and New York City Department of Information Technology and Telecommunications, *700 MHz Broadband Public Safety Applications And Spectrum Requirements* (February 2010). This report offers compelling evidence about the spectrum capacity needed to support the public safety community. Squeezing public safety into a narrow slice of spectrum that would not permit the effective leveraging of commercial broadband technologies, including the crucial evolution to LTE technology (that must have 20MHz), and would deny the spectrum for the essential "paired bands" of 2x10MHz.

We recognize that there would likely be numerous sensible ways to structure the commercial lease transactions. We do not have a specific brief for how the D Block spectrum is to be managed nor do we write to advocate how revenue from such commercial transactions should ultimately be allocated. We also understand that a national broadband policy that protects the needs of first responders will need the support of Congress as well as that of the FCC.

We are convinced, however, that the FCC's proposed broadband plan seriously shortchanges the first responder community and simply will not give these vital public servants adequate spectrum to do their jobs when it matters most, during times of crisis. Therefore, we respectfully request that FCC reconsider its proposed D Block allocation proposal and instead support allocation of the D Block to public safety providers.

Thank you for your consideration of this important policy matter.

HARRIS

D Block Spectrum Should be Reallocated to Public Safety

Harris Corporation ("Harris") supports the public safety community's request for legislative action to reallocate the 10 MHz of spectrum known as the D-Block for public safety use. Such a reallocation, combined with the 10 MHz of spectrum already allocated for public safety use, will create a contiguous, nationwide 20MHz swath of broadband spectrum for wireless public safety applications. With Congress' leadership and financial support Harris believes that the nation's goal for a 700MHz nationwide, interoperable broadband public safety network can be realized and our nation's first responders will be afforded the same state-of-the-art communications technology as the citizens they protect.

In 2008 the D-Block, in accordance with congressional mandate, was put up for commercial auction. In accordance with Federal Communications Commission ("FCC") rules the D-Block was to be paired with an adjacent block of broadband spectrum allocated to Public Safety to create a shared wireless broadband network that would be used by public safety users as well as commercial users. The winning bidder of the commercial license in the D-block would be obligated to enter into a public/private partnership with the nationwide licensee of the public safety broadband spectrum to enable construction of this interoperable broadband network. Unfortunately, the D-Block auction was a failure and did not produce a D-Block commercial licensee. Today, even following the completion of the digital television transition, both the D-Block and public safety broadband spectrum lay fallow.

Along with the public safety community, Harris has publicly stated its support of and made numerous recommendations addressing how to establish a nationwide, interoperable broadband public safety network in both comments filed with the FCC and through invited participation in FCC hearings. Although 10 MHz may be useful, Harris believes that a full <u>20 MHz</u> of dedicated public safety broadband spectrum is necessary to fully accommodate the bandwidth intensive broadband applications required by public safety users and first responders.

The FCC envisioned the 700 MHz public safety broadband network as a wide-area, mobile broadband data solution.[i] While the 10 MHz of spectrum currently allocated to public safety will satisfy many public safety mobile broadband needs,[ii] this spectrum allocation may be insufficient to accommodate some of the envisioned uses for the network. For example, as outlined in the SAFECOM Statement of Requirements for Public Safety Wireless Communications and Interoperability, broadband networks are expected to carry surveillance video from fixed surveillance cameras throughout a city to public safety vehicles in the field.[iii] Today, "the available 5 MHz of public safety uplink spectrum can accommodate only a limited number of cameras per cell before these fixed wireless video applications exhaust the spectrum" (typical IP surveillance video operates at 500 kbps–1.5 Mbps).[iv]

A shared network concept (10MHz + 10MHz) governed through a national public/private partnership between commercial and public safety at first appeared to be the most logical path to fund a nationwide, interoperable broadband public safety network. However, the failure of the D-Block auction and resulting uncertainty surrounding the future of the shared wireless broadband network has prevented the deployment of critically needed public safety broadband systems. Nevertheless, in recent months the public safety community has started to take action on the local and regional level to develop and deploy public safety broadband systems. There are currently 16 outstanding waiver requests from local jurisdictions before the FCC requesting immediate access to the 700 MHz public safety broadband spectrum to deploy broadband systems. In addition, a handful of public safety entities are looking to the future by including broadband capabilities in their planning for new public safety communications systems.

Although Harris continues to support the creation of a nationwide, interoperable broadband public safety network, it is becoming increasingly clear that a regional, network of networks approach, will best serve to accelerate the general deployment of public safety broadband. The call for regional flexibility for the use and deployment of public safety broadband systems has been endorsed by many public safety organizations including the Public Safety Spectrum Trust Corp ("PSST") and the National Public Safety Telecommunications Council ("NPSTC"). However, achieving the goal of a nationwide broadband interoperable network for public safety will be ultimately dependent upon funding available for all public safety entities, including those serving rural areas, to access spectrum, deploy technology and connect to the network.

Furthermore, Harris agrees with NPSTC's recommendations set forth in the Broadband Task Force Report ("BBTF") urging Congress and the FCC to "explicitly allow use of the national interoperable broadband wireless network in spectrum allocated to public safety by not only first responders, but also by emergency response support agencies (such as utilities, transportation, certain Federal government agencies, and general government)."[v] Not only do these public service agencies provide critical emergency response during local, regional and national disasters, they represent the very real potential for public and private partners in rural areas to realize cost and coverage benefits through shared systems.

The nation's goal for wide scale use of broadband and national communications interoperability rests in the wise use of spectrum and the creation of a 700 MHz nationwide interoperable wireless broadband public safety network. Congress has the ability, and the responsibility, to take the action to assign the D-Block to our nation's first responders so that they can better serve the citizens they protect.

About Harris Corporation

Harris is an international communications and information technology company serving government and commercial markets in more than 150 countries. Headquartered in Melbourne, Florida, the company has approximately $5 billion of annual revenue and more than 15,000 employees — including nearly 7,000 engineers and scientists. Harris is dedicated to developing best-in-class *assured communications*® products, systems, and services. Additional information about Harris Corporation is available at www.harris.com.

JENNIFER M. GRANHOLM
GOVERNOR

State of Michigan
STATE 9-1-1 COMMITTEE
LANSING

SHERIFF DALE GRIBLER
CHAIR

September 22, 2010

The Honorable Carl Levin
United States Senator
269 Russell Senate Office Bldg
Washington, DC 20510

Dear Senator Levin:

As the state committee tasked by the Michigan Legislature to develop statewide standards and make recommendations on 9-1-1 service, we urge you to support S. 3756, the Public Safety Spectrum and Wireless Innovation Act of 2010, introduced by Senator John (Jay) Rockefeller, IV (D – WV), Chairman of the Senate Commerce, Science, and Transportation Committee. The Public Safety Spectrum and Wireless Innovation Act would:

- Establish a framework for the deployment of a nationwide interoperable wireless broadband network for public safety;
- Allocate 10 MHz of spectrum, known as the D Block, to public safety;
- Direct the Federal Communications Commission (FCC) to develop technical and operational standards to ensure nationwide interoperability and build-out (including in rural areas);
- Direct the FCC to establish standards that allow public safety officials, when not using the network, to lease capacity on a secondary, but preemptive basis to non-public safety entities, including other governmental users and commercial users; and
- Provide the FCC with incentive auction authority, which allows existing spectrum licensees to voluntarily relinquish their airwaves in exchange for a portion of the proceeds of the commercial auction of their spectrum. The funds from these incentive auctions, in conjunction with funds from the auction of other specified spectrum bands, and funds earned from leasing the public safety network on a secondary basis, will be used to fund the construction and maintenance of the nationwide interoperable wireless broadband public safety network.

This legislation builds on the growing support in Congress from Senators Joe Lieberman (I – Conn.) and John McCain (R – Ariz.) who introduced S. 3625 – The First Responders Protection Act of 2010; Representatives Peter King (3rd Dist., NY) and Yvette Clarke (11th Dist., NY), who introduced H.R. 5081 – Broadband for First Responders Act of 2010, which now has more than 68 cosponsors; and Representative Henry Waxman (30th Dist., CA), Chairman of the House Energy and Commerce Committee, whose draft language was the catalyst to identifying the necessary funding to build out and maintain a nationwide interoperable public safety broadband network.

Public safety officials, including 9-1-1 directors, police chiefs, sheriffs, fire chiefs, police officers, fire fighters, and emergency medical service officials in Michigan are strong in their support for the allocation of the D Block to public safety and the establishment of a funding program. Given the limited nature of radio spectrum, if the allocation of D Block does not occur now, it may be decades before another opportunity like this comes to public safety. The allocation of the D Block and the funding program to construct and maintain a nationwide interoperable wireless broadband network will improve our nation's homeland security and provide first responders throughout the country with the voice, video, and data communications technologies that are urgently needed.

Thank you for your support of our nation's first responders who put their lives on the line every day to protect and serve our communities. If you have any questions, or would like additional information on the D Block issue, please contact the State 9-1-1 Committee through the State 9-1-1 Administrator, Harriet Miller-Brown, at 517-241-0080 or millerhr@michigan.gov.

Sincerely,

Sheriff Dale Gribler, Chair
State 9-1-1 Committee

InterAgency Board (IAB)
Position Statement on the "D" Block Public Safety Spectrum

The state and local first responders of the InterAgency Board for Equipment Standardization and Interoperability (IAB) formally support the efforts of the Public Safety Alliance (http://www.psafirst.org/) to secure the allocation of the 700 MHz "D" Block spectrum for public safety use.

The InterAgency Board is a voluntary collaborative panel of emergency preparedness and response practitioners from a wide array of professional disciplines that represent all levels of government and the volunteer sector. The IAB provides a structured forum for the exchange of ideas among operational, technical, and support organizations to improve national preparedness and promote interoperability and compatibility among local, state, tribal and federal response communities. Based on direct field experience, IAB members advocate for and assist the development and implementation of performance criteria, standards, test protocols, and technical, operating, and training requirements for all-hazards incident response equipment with a special emphasis on Chemical, Biological, Radiological, Nuclear, and Explosive (CBRNE) issues.

The Interagency Board works hard everyday to promote interoperability across all fields within the first responder community; because of this the first responders of the IAB readily recognize that the allocation of the "D" block directly to public safety is an important national priority. First responders across this nation need a data network that has the ability to seamlessly roam across this great nation. The vision of a single interoperable national broadband public safety network is attainable within our lifetime if public safety is provided the appropriate resources. The key variable for this capability is the allocation of the "D" block. While the journey may be long, it begins with the establishment of a single national public safety broadband plan that all of public safety can build on, as resources become available. Public safety agencies need the 10MHz D block spectrum, in addition to the 10 MHz of broadband spectrum already allocated and licensed to public safety, to meet their critical requirements.

The first responders on the InterAgency Board commend the Public Safety Alliance for their leadership and efforts in securing the "D" Block for the first responder community.

July 13, 2011

The Honorable John D. Dingell
United States House of Representatives
Washington, DC 20510

The Honorable Gene Green
United States House of Representatives
Washington, DC 20510

Dear Congressmen Dingell and Green:

On behalf of the International Association of Chiefs of Police (IACP), I am writing to express our strong support of H.R. 2482, the Public Safety Spectrum and Wireless Innovation Act.

H.R. 2482 would provide law enforcement and other public safety agencies with an additional 10 megahertz (MHz) of spectrum that is necessary to support a nationwide, interoperable, wireless broadband network that will help them fulfill their mission of protecting lives in communities throughout the United States.

Law enforcement and public safety must have a minimum of 20 MHz of broadband spectrum to meet current and future needs and must have access to new technologies to perform increasingly complex duties. These technologies must have adequate and dedicated spectrum that is managed and controlled by public safety to ensure that they will be more secure and reliable than commercial broadband systems. The D-Block allocation to public safety and federal funding is essential if we are to meet the critical needs of our nation's law enforcement and public safety community.

The IACP stands ready to assist you in any way possible. Our representative in this matter is Chief Harlin R. McEwen, Chairman of the IACP Communications & Technology Committee, and he can be contacted at chiefhrm@pubsaf.com or (607) 227-1224.

Thank you for your leadership in this matter.

Respectfully,

Mark A. Marshall
President

July 8, 2011

The Honorable John D. Dingell
2328 Rayburn House Office Building
U.S. House of Representatives
Washington, D.C. 20515-2215

Dear Congressman Dingell:

On behalf of the more than 14,000 members of the Association of Public-Safety Communications Officials (APCO) International and the 200,000 public safety professionals we serve each year, we strongly support your introduction of companion legislation to the bipartisan Senate bill, S. 911 – the *Public Safety Spectrum and Wireless Innovation Act of 2011*, which was recently favorably voted out of the Senate Commerce Committee on a 21-4 vote with overwhelming bipartisan support.

As a senior member and former Chairman of the House Committee on Energy and Commerce, your introduction of this companion bill includes key legislative principles that the public safety, first responder and state and local government communities have championed as a top priority issue for Congress to enact this year ahead of the the 10th Anniversary of the tragic events of 9/11. Specifically, your legislation would: (1) allocate the entire 10 MHz D Block within the 700 band to public safety, (2) reauthorize the Federal Communications Commission to conduct spectrum auctions in the future to boost the economy and raise revenue to pay down the debt and fund other programs, and (3) authorize voluntary incentive auctions to generate tens of billions in new revenue, including up to $10 billion for debt reduction and $11 billion to help fund the nationwide interoperable public safety broadband network. Much like S.911, your legislation meets an outstanding recommendation of the bipartisan 9/11 Commission, as recently reiterated in testimony before Congress.

We thank you for your leadership in sponsoring this critical legislation. We urge the House Energy and Commerce Committee to move swiftly to co-sponsor and pass this legislation in order to bring it to the House floor immediately. We look forward to working with you on this top priority public safety issue in the coming days and weeks toward final enactment ahead of the 10th Anniversary of 9/11.

Sincerely,

William D. Carrow
President

Gregory T. Riddle
First Vice President

D. Terry Hall
Second Vice President

Richard A. Mirgon
Immediate Past President

KENWOOD
Listen to the Future

Kenwood USA Corporation supports the allocation of the D Block to public safety to improve our nation's homeland security and provide first responders with new voice, video, and data communications technologies that are urgently needed. Senate Commerce Committee Chairman John "Jay" Rockefeller, IV of West Virginia recently introduced legislation, **S. 3756: The Public Safety Spectrum and Wireless Innovation Act of 2010**, which provides the basis for implementing this unmet 9/11 Commission recommendation.

Our country's local, State, Tribal, and Federal law enforcement, fire, medical, and other emergency professionals must have access to the most modern and reliable wireless broadband technologies and spectrum to communicate with each other during emergencies. The ability for public safety to have seamless -roaming capability on a wireless broadband network that is hardened to public safety requirements is achievable and essential for public safety to meet its ever increasing responsibilities.

The Federal Communications Commission (FCC) is planning to address this issue again by the disposition of the D Block via auction. The first attempt by the FCC to auction the spectrum was unsuccessful. Public safety officials, service providers and infrastructure vendors agree that a more effective method would be to allocate the D Block directly to public safety organizations to meet the critical needs of first responders.

If allocated this additional 10 MHz of spectrum, the D block will be combined with the current 10 MHz of spectrum already allocated to public safety to create a 20 MHz block, enough to build public safety broadband network(s). When built, the network will be able to support a broad range of public safety, government, critical infrastructure and voice, video, and data services. The envisioned public/private partnership will also provide much needed public safety service, as well as broadband service, to rural America.

One of the top recommendations of the "9/11 Commission Report" was for Congress to "support pending legislation which provides for the expedited and increased assignment of radio spectrum for public safety purposes." We believe Congress must quickly pass legislation to allocate the D block spectrum to public safety, as first proposed in bipartisan legislation introduced by Congressman Peter King (R-NY) and Congresswoman Yvette Clarke (D-NY) as **H.R. 5081: Broadband for First Responders Act of 2010.** S. 3756 builds upon H.R. 5081, as well as **S. 3625: The First Responders Protection Act of 2010,** as introduced by Senate Homeland Security Committee Chairman Senator Joe Lieberman and former Senate Commerce Chairman John McCain.

Our nation cannot afford to miss this one-time-only opportunity and we call on Congress to support our first responders who put their lives on the line every day to protect and serve their communities.

Sincerely,

Kenwood U.S.A. Corporation
Communications Sector

THE CITY OF NEW YORK
OFFICE OF THE MAYOR
NEW YORK, NY 10007

June 7, 2011

The Honorable John D. Rockefeller
Chairman
Committee on Commerce, Science, and Technology
United States Senate
Washington, DC 20510

The Honorable Kay Bailey Hutchison
Ranking Member
Committee on Commerce, Science, and Technology
United States Senate
Washington, DC 20510

Dear Chairman Rockefeller and Ranking Member Hutchison:

I am writing in strong support of S. 911, the Strengthening Public-Safety and Enhancing Communications Through Reform, Utilization, and Modernization (SPECTRUM) Act, a bipartisan initiative crucial to the future of public safety in the United States.

In the aftermath of the attacks on September 11, 2001, Americans came to understand that a commitment to comprehensive improvement in our system of emergency communications is an essential element of our national security. New York City has worked tirelessly to make interoperability of emergency communications a reality, and we have made significant progress on that goal, but our efforts are necessarily limited to a local level. As we approach the 10th anniversary of 9/11, we can no longer afford to leave this issue—one of the key areas of focus of the 9/11 Commission—unaddressed. Legislation setting aside a dedicated portion of the 700 MHz spectrum for public safety officials for a nationwide interoperable network—known as the D Block—must be passed immediately to aid first responders across the country and at every level in saving countless lives and ensuring homeland security.

Building a nationwide broadband public safety network would allow cities across the country to transmit critical, real-time information during emergencies. In New York City, we have achieved interoperability for emergency voice communications, ensuring that all of our emergency responders can communicate in real time over our local radio systems. But that same interoperability needs to be able to function beyond individual localities, to provide seamless communication nationwide, which can only be accomplished with adequate public safety spectrum.

The SPECTRUM Act would not only provide interoperable voice communication, but also bring the technology used by public safety agencies into the twenty-first century, allowing for critical data of all types to be shared among those who need it while responding to emergencies. The additional spectrum would allow our police officers, firefighters, and emergency medical teams to instantly access relevant floor plans, maps, and photos to aid in search efforts for survivors, and our EMS workers would be able to wirelessly relay patient information to hospitals while en route. Rather than relying on bits and pieces of scattered spectrum that would prevent large data transmissions, every local, state, and federal first responder would be linked seamlessly on the D Block. Establishing this coast-to-coast communications network is a crucial tool in continuing efforts to combat all of the challenges that our public safety professionals face, from international terrorism to local weather emergencies.

Allocating the D Block spectrum for the exclusive use of the nation's emergency responders benefits not only the public safety officers who risk their lives while performing their duties, but helps every American who they serve in time of need. I look forward to working with you and your colleagues to ensure passage of legislation establishing a public safety broadband network this year.

Thank you for your consideration of this critically important issue.

Sincerely,

Michael R. Bloomberg

Michael R. Bloomberg
Mayor

Motorola Supports Public Safety Coalition and Offers Six Point Plan to Make Public Safety Broadband a Reality

Background

The need for additional spectrum for public safety data and video communications has long been recognized. From the Public Safety Wireless Advisory Committee Report released on September 11, 1996, to the 9/11 Commission report in 2005, to a failed D block auction nearly two years ago, there has been broad public and private sector support for providing public safety with the resources necessary to meet its communications requirements. The right combination of rules, spectrum and funding to bring the public safety broadband network to reality is long overdue. Motorola supports the coalition of major public safety organizations encouraging such action.

Motorola's Position

Motorola recommends the following six point plan to enable the implementation of public safety broadband communications that meet both operability and interoperability requirements:

1. Legislation: Pass legislation reallocating the 700 MHz D block for public safety use and add that spectrum to the nationwide Public Safety Broadband License (PSBL) held by the Public Safety Spectrum Trust (PSST).

2. Funding: Identify sources of funding, including multi-year Federal appropriations as needed, to enable deployment and maintenance of the public safety broadband network, as well as implementation of the nationwide framework for interoperability.

3. Regulatory Structure: Adopt a regulatory structure that enables deployment by public safety host agencies that need to control their own regional system. This structure should also include third parties serving agencies who are unable to deploy, operate or maintain their own system. These host agencies or designated third parties would serve all public safety agencies in their respective region who want access to the broadband network under spectrum use agreements with the PSST.

4. Interoperability Framework: Establish a national framework for interoperability that the PSST would administer through spectrum use agreements with public safety host agencies that want to deploy regional networks. This framework would include designation of Long Term Evolution (LTE) as a common radio access network technology nationwide and a basic set of broadband software applications all agencies would have for interoperability.

5. User Choice: Provide all agencies using the network the right to choose and deploy their own interoperable portable/mobile devices and software applications in addition to those designated for interoperability.

6. Inclusion and Prioritization: Permit Federal, state/local public service functions, and critical infrastructure entities as users on the public safety broadband network to enhance interoperability. Allow host agencies, in coordination with these users and the PSST, to set prioritization among the various users as required, a capability LTE technology can provide.

Benefits of the Plan

Reallocating the D block and adding it to the PSST's license provides 20 MHz of spectrum for public safety broadband communications to support the delivery of high speed data and video information. When added to the continued use and deployment of mission critical voice systems, public safety can have the full range of communications tools needed, all designed with the security and reliability essential to meet operational requirements. While this is a modest amount of spectrum in the context of broadband, the D block will provide public safety the capacity needed in urban areas and will enable broadband speeds in rural areas with fewer transmit sites, resulting in lower costs. Adding the D block also helps provide the capacity needed to enable improved interoperability across multiple levels of government – local, state and Federal – especially in times of crises events when all networks are typically stressed to their peak capacity.

Motorola joins public safety representatives in their call for Congress to identify sources of funding to deploy and maintain the public safety broadband network. Throughout history, making major infrastructure deployments a reality has necessitated Federal funding support in some form.

This six point plan sets forth the framework to adopt rules providing public safety with the control and flexibility required to deploy broadband systems that meet unique regional operability needs, while maintaining the degree of commonality for nationwide interoperability.

As this Administration and Congress take action to enable broadband to the general public, it should also act now to enable broadband systems for the unique needs of the public safety community.

MOTOROLA

October 7, 2010

The Honorable John D. Rockefeller
Chairman
Committee on Commerce, Science and Transportation
United States Senate
Washington, D.C. 20510

Dear Chairman Rockefeller:

Motorola fully supports reallocation of the D-Block to Public Safety and asks Congress to pass legislation to give Public Safety this additional spectrum.

This is a unique moment in time where the FCC has made a commitment to the funding and building of a nationwide, interoperable Public Safety wireless broadband network to advance the services available to Public Safety. Losing the D Block by auctioning it to a private carrier will make Public Safety vulnerable because Public Safety won't be able to implement the much needed next generation technologies. It will restrict the ability to keep communities safe and it will increase the vulnerability of law enforcement, fire and EMS personnel across the country.

Our law enforcement officers, fire fighter and EMS personnel deserve the latest technology available to help them do their jobs. Thorough evaluation by industry leading suppliers, experts, carriers and Public Safety agencies has clearly established that the D Block should be rejoined with the Public Safety Spectrum Trust (PSST) and dedicated to law enforcement, fire and EMS to enable capacity for 21st century Public Safety broadband applications.

Furthermore, studies have established that reallocation will ensure that interference and the resulting service holes are mitigated and that full control and prioritization of broadband resources are necessary for optimal Public Safety response. But these studies have been rejected by the FCC and they have directed Public Safety to roam on commercial carriers for additional spectrum. Accountability without control endangers lives. This cannot be allowed to happen.

Public Safety has demonstrated the need for additional spectrum and without control and priority of that spectrum during day-to-day and emergency incidents; commercial interests are put above that of Public Safety.

We are proud to partner with our public safety customers and look forward to continuing to provide them with the next generation tools they need to serve and protect their communities.

August 26, 2011

The Honorable Harry Reid
Senate Majority Leader

The Honorable Mitch McConnell
Senate Republican Leader

The Honorable John Boehner
Speaker of the House of Representatives

The Honorable Nancy Pelosi
House Democratic Leader

Sent via email

Dear Majority Leader Reid, Senator McConnell, Speaker Boehner and Leader Pelosi:

The 112th Congress is considering the passage of several bills on D-Block wireless communication that would allocate a specific broadband spectrum to public safety, designating this bandwidth for law enforcement use - and finally creating the truly interoperable communications network that law enforcement and emergency responders have needed for decades.

We understand that Congress may take action on this important legislation prior to the 10th anniversary of the September 11 terrorist attacks. Nothing could be more appropriate than marking this solemn anniversary by making a genuine commitment to public safety communication, for this and future generations.

Rather than endorsing any one proposal now under consideration, in the spirit of bi-partisanship the nation's attorneys general urge you to protect citizens across all our states - by ensuring that the public safety professionals who have committed to serve and protect can effectively communicate with one another in the face of a dire emergency or attack.

Even without the constant threat of terrorist acts, repeated natural disasters in recent years have driven home the need in state after state. In Mississippi, Attorney General Jim Hood has seen his state endure Hurricanes Katrina and Ike, flooding of the Mississippi River Delta and a class 5 tornado that obliterated the town of Smithville. Immediately after Katrina, communications between Jackson, the capital city in the middle of the state, and the Mississippi Gulf Coast were minimal with no electricity and few cell phones. Gasoline was in high demand, and his office sent truck loads to the Coast along with satellite phones.

In more sparsely populated rural states like Montana, communication among law enforcement agencies is further complicated by the number of jurisdictions involved. Floods like those the Western states experienced this spring and the raging forest fires we face each summer have no regard for the patchwork of private, state, federal and tribal lands they devastate.

By providing the resources to develop a reliable, rapid and comprehensive law enforcement wireless communications system, the D-block designation would serve all our citizens well.

On April 12, 2011, the House Committee on Energy and Commerce held a hearing to find uses for the spectrum that would advance public safety, promote broadband, create jobs and reduce the deficit. Speakers before the House Committee recommended that part of the spectrum freed when media companies changed to digital, 768-763 megahertz and 788-793 megahertz, be designated for first responders and public safety. Officials told Congress that, were the FCC to auction the remainder of the broadband to Internet providers, the monies realized could be allocated to infrastructure and made available for sorely needed law enforcement support.

According to the FCC, the need to designate the spectrum for law enforcement purposes is made more urgent by an already burgeoning information flow. Communication devices like cell phones, netbooks and smart phones are increasing by an astonishing growth rate of over 250 percent each year. For example, over 13 billion new smart-phone applications have been downloaded. By freeing increased, unlicensed spectrum, D-Block legislation will create innovation and growth, encourage the development of new media, and increase wireless networks in rural areas by private industry.

Ultimately, reallocation of the spectrum use should benefit consumers by lowering transaction costs and increasing communication industries, all while supporting law enforcement and increasing public safety. The importance of designating the D-Block spectrum for law enforcement simply cannot be overstated.

The result for the greater good of national safety trumps any partisanship. For that reason, 42 of our nation's attorneys general urge your strong support of legislation that will give our law enforcement officers and emergency responders the reliable wireless communication our nation has long needed.

Thank you for your consideration.

Sincerely yours,

Jim Hood

NORTHROP GRUMMAN

Northrop Grumman Supports the Reallocation of the 700 MHz D Block Spectrum to Public Safety

The role of first responders has changed dramatically since the tragic events of September 11, 2001, and yet very little progress has been made toward placing advanced mobile technology into the hands of the nation's emergency services personnel. Public safety applications and technologies are advancing rapidly, and yet the ability to apply this technology to a highly mobile workforce has been hampered by the lack of spectrum in which to build a nationwide network. The need for spectrum has never been greater for data, voice and incident video for the short term and the future. Sufficient spectrum needs to be allocated to allow for manufacturers to develop secure wireless systems that will not be obsolete before they are fully deployed.

Congress and the Federal Communications Commission (FCC) have a unique opportunity to provide public safety with the right amount of spectrum to foster development of new technologies to enhance the safety of our first responders and provide them with the tools to carry out their mission effectively and efficiently. Northrop Grumman supports the reallocation of the D Block to public safety and the establishment of regulatory process and structure that will allow fully interoperable networks to be constructed by regions, states and government entities that will commit to building and managing such systems. We support the public safety coalition's efforts to request Congressional action to reallocate the D Block to public safety creating spectrum foundation for the future.

Northrop Grumman further supports the licensing of the full 20 MHz of spectrum to individual entities that are capable of implementing and managing the network as a sub-licensee to the already established Public Safety Spectrum Trust. The FCC should adopt regulatory policy that enables early deployment of secure broadband networks provided the managing agency conforms to the national standards allowing full compatibility with devices and interoperability with supporting agencies. The regulatory structure of the nationwide network must be flexible enough to allow for public/private partnerships where practical, and options that allow first responders to have access to a broadband network built to public safety standards for reliability and redundancy. Additionally the region or entity constructing the network should have the option to include other governmental users as practical to take advantage of the networks' capabilities. The widely adopted Long Term Evolution (LTE) standard includes priority access and a quality of service (QoS) hierarchy that will ensure that public safety standards for access are met.

The federal government also needs to identify funding sources to enable the construction and management of the nationwide network, and the adoption and compliance of a national standard for interoperability. We also support the establishment of a governing body that maintains and manages the interoperability components of the network such as authentication and priority access to ensure that the true purpose of the network is upheld. The rules must permit the participation of both federal and local public safety first responders, public service / governmental agencies, and critical infrastructure partners to allow for true interoperability and cost sharing among high priority and low priority users.

Northrop Grumman stands with the public safety community in asking Congress to immediately begin identifying funding mechanisms to ensure that construction of the nationwide network is commenced as soon as practicable. As the country focuses on strengthening the economy and securing our nation from further attacks we need to place emphasis on improving the capabilities of our first responders through technology. The Administration has a unique opportunity to set a precedent for public safety by allocating the right amount of spectrum for the near term and the future of public safety communications.

NORTHROP GRUMMAN

Northrop Grumman Information Systems
Washington Operations
1000 Wilson Blvd.
Suite 2300
Arlington, Virginia 22209

October 1, 2010

The Honorable John D. Rockefeller
Chairman
Committee on Commerce, Science and Transportation
United States Senate
Washington, D.C. 20510

Dear Chairman Rockefeller:

Northrop Grumman supports Senate Bill S.3756 -- Public Safety Spectrum and Wireless Innovation Act. The bill seeks to amend the Communications Act of 1934 to provide public safety officials an additional 10 megahertz of spectrum to support a national, interoperable wireless broadband network and authorize the Federal Communications Commission to hold incentive auctions to provide funding to support such a network, and for other purposes.

Northrop Grumman believes strongly that the actions called for in the bill, to provide additional broadband spectrum to Public Safety contiguous to their existing spectrum allocation and to provide funding for a national broadband network for Public Safety, are vital steps to provide first responders across the United States with the tools they need. The development and deployment of new mobile broadband technologies for the commercial wireless marketplace provides the possibility for Public Safety to leverage a vast array of technology to improve safety and efficiency of our entire Homeland Security infrastructure. The U.S. government is wise to leverage this opportunity in time to provide consistent, contiguous broadband spectrum to Public Safety. If the "D" block spectrum is auctioned to the private sector it cannot be recovered, and as critical application requirements of those who protect us increase it will be impossible to provide a cost effective solution to future mission requirements.

Northrop Grumman encourages the Congress and the Administration to enthusiastically support this important transformation of the future Public Safety communications system.

Sincerely,

Hugh E. Taylor
Sector Vice President, Washington Operations
Northrop Grumman Information Systems

NATIONAL SHERIFFS' ASSOCIATION

July 10, 2011

The Honorable John D. Dingell
U.S. House of Representatives
Washington, D.C. 20515

Dear Congressman Dingell:

On behalf of the National Sheriffs' Association (NSA) and the 3,083 elected sheriffs nationwide, we are writing to express our strong support for your introduction of the Public Safety Spectrum and Wireless Innovation Act in the U.S. House of Representatives. This legislation serves as a companion bill to S. 911 – SPECTRUM Act, introduced by Senator Jay Rockefeller (D-WV) and Senator Kay Bailey Hutchison (R-TX) in the Senate.

The Public Safety Spectrum and Wireless Innovation Act includes key legislative principles that both the public safety; and state and local government communities have requested as a top priority issue for Congress to enact this year, ahead of the 10th Anniversary of the tragic events of 9/11.

Specifically, your legislation would: allocate the D Block to public safety for the creation and implementation of a nationwide public safety interoperable mobile broadband network; reauthorize the Federal Communications Commission (FCC) to conduct spectrum auctions in the future to boost the economy and raise revenue to pay down the debt and fund other programs; and authorize voluntary incentive auctions to generate tens of billions in new revenue for not only debt reduction, but to fund the nationwide interoperable public safety broadband network.

Congressman Dingell, like S. 911, your legislation meets a still outstanding recommendation of the bipartisan 9/11 Commission. The nation's sheriffs thank you for your leadership in sponsoring this critical legislation, and we stand ready to assist you in enacting this vital legislation before the 10th Anniversary of 9/11.

Sincerely,

Paul H. Fitzgerald

Sheriff Paul H. Fitzgerald
President

Senator Maria Cantwell
311 Hart Senate Office Building
Washington, D.C. 20510

Dear Senator Cantwell:

As the Chief of the Olympia Police Department, I am writing to advise you of my strong support of the Public Safety Spectrum and Wireless Innovation Act (S. 28), sponsored by Senator Jay Rockefeller (D-WV). The legislation will allocate D-Block spectrum to public safety for the development of a nationwide interoperable public safety broadband network and designate significant funds to build out and operate the nationwide network.

Law enforcement and public safety must have a minimum of 20 MHz of broadband spectrum to meet current and future needs and must have access to new technologies to perform increasingly complex duties. These technologies must have adequate and dedicated spectrum that is managed and controlled by public safety to ensure that they will be more secure and reliable than commercial systems. The D-Block allocation and funding is essential if we are to meet the critical needs of our nation's law enforcement and public safety community.

I am proud to support S. 28, and I urge you to support our efforts as well.

Best Regards,

Ronnie Roberts, Chief
Olympia Police Department

INTERNATIONAL ASSOCIATION OF FIRE CHIEFS

Providing leadership for the fire and emergency services since 1873

4025 FAIR RIDGE DRIVE • FAIRFAX, VA 22033-2868 • TEL: 703/273-0911 • FAX: 703/273-9363 • www.iafc.org

July 11, 2011

The Honorable John D. Dingell
2328 Rayburn House Office Building
U.S. House of Representatives
Washington, DC 20515

Dear Congressman Dingell:

On behalf of the nearly 13,000 chief fire and emergency officers of the International Association of Fire Chiefs (IAFC), I am writing to express our strong support for your introduction of H.R. 2482, the Public Safety Spectrum and Wireless Innovation Act, as a companion to S. 911, the Strengthening Public-safety and Enhancing Communications Through Reform, Utilization, and Modernization Act. This legislation would fulfill one of the outstanding recommendations of the 9/11 Commission, and improve the nation's response to future national disasters, both natural and man-made.

Your legislation includes key legislative principles that the first responders and state and local governments have designated as a top priority for passage before the tenth anniversary of the tragic events of September 11, 2001. Specifically, it would allocate the 10 MHz of the D Block in the 700 MHz band to public safety for the creation and implementation of a nationwide public safety wireless broadband network and authorize the Federal Communications Commission (FCC) to conduct voluntary incentive spectrum auctions to fund the construction, operation and maintenance of the public safety wireless broadband network and reduce the federal deficit.

The IAFC thanks you for your leadership in sponsoring this critical legislation. We look forward to working with you and the other members of the House Energy and Commerce Committee to pass H.R. 2482 in order to bring it to the House Floor. It is vitally important that Congress address this remaining recommendation of the 9/11 Commission before September 11, 2011.

Sincerely,

John E. Parow

Chief Jack Parow, MA, EFO, CFO
President and Chairman of the Board

Public Safety Alliance
Dedicated to First Responders...First

July 8, 2011

The Honorable John D. Dingell
2328 Rayburn House Office Building
U.S. House of Representatives
Washington, D.C. 20515-2215

Dear Congressman Dingell:

On behalf of the more than 2 million first responders nationwide, the Public Safety Alliance strongly supports your introduction of companion legislation to Senate bill S. 911 – the *Public Safety Spectrum and Wireless Innovation Act of 2011*, which was recently favorably voted out of the Senate Commerce, Science and Transportation Committee on a 21-4 vote with overwhelming bipartisan support.

As a senior Member and former Chairman of the House Committee on Energy and Commerce, your introduction of this companion bill includes key legislative principles that the public safety, first responder and state and local government communities have requested as a top priority issue for Congress to enact this year ahead of the the 10th Anniversary of the tragic events of 9/11. Specifically, your legislation would: (l) allocate the entire 10 MHz D Block within the 700 band to public safety and allow it to be combined with 10 MHz already allocated to public safety for broadband, (2) reauthorize the Federal Communications Commission to conduct spectrum auctions in the future to boost the economy and raise revenue to pay down the debt and fund other programs, (3) authorize voluntary incentive auctions to generate tens of billions in new revenue of up $10 billion for debt reduction and $11 billion to help fund the nationwide interoperable public safety broadband network. Like S.911, your legislation meets a still outstanding recommendation of the bipartisan 9/11 Commission, as recently reiterated in testimony before Congress by their bipartisan co-chairs.

We thank you for your leadership in sponsoring this critical legislation. We urge the House Energy and Commerce Committee to swiftly co-sponsor and pass this legislation in order to bring it to the House floor immediately. We look forward to working with you on this top priority public safety issue in the coming days and weeks toward final enactment ahead of the 10th Anniversary.

Sincerely,

The Public Safety Alliance Leadership

August 5, 2011

The Honorable Harry Reid
United States Senate
522 Hart Senate Office Bldg
Washington, DC 20510

Dear Senator Reid,

On behalf of the Nevada Fire Chiefs Association and the Nevada fire service, we want to express our gratitude for your continued support of S. 911, the Strengthening Public-safety and Enhancing Communications Through Reform, Utilization, and Modernization Act (SPECTRUM) Act. This bill, introduced by Senators John D. "Jay" Rockefeller, IV and Kay Bailey Hutchison, will ensure that public safety organizations have the necessary spectrum to develop a nationwide public safety interoperable wireless broadband network.

The broadband revolution presents America's fire service with the opportunity to take advantage of new technology to greatly enhance public safety communications. For example, wireless broadband access will enable the development and widespread adoption of devices to track firefighters inside burning buildings; allow smart buildings to broadcast information about a fire to a fire chief's cell phone; allow paramedics to share a patient's vitals remotely with medical staff at a hospital; and much more. In order to access this new technology across the country, the federal government must support the development of a nationwide public safety interoperable wireless broadband network.

Currently, public safety has been licensed 10 MHz of spectrum to develop a nationwide public safety wireless broadband system. There is another block of 10 MHz of spectrum (the "D Block") adjacent to public safety's broadband spectrum. S. 911 would allocate the D Block to public safety which could then work with the private sector to develop a nationwide public safety interoperable wireless broadband network using 20 MHz of spectrum. Unfortunately, current law directs the Federal Communications Commission to auction the D Block to a commercial bidder.

S. 911 will prevent the auction of the D Block, and instead allocate it directly to public safety to build out its nationwide wireless broadband network. Considering that there is a shortage of spectrum, S. 911 presents public safety with its only opportunity to obtain the critical spectrum that it needs to bring cutting-edge technology to America's firefighters, police officers, and emergency medical personnel.

I urge you to continue your support of S. 911, so that public safety can develop a nationwide public safety interoperable wireless broadband network to more effectively protect the American public. This is a one-time only opportunity to get it right. Your help is essential.

Sincerely,

Robert S. Giomi

Stacey Giomi, Fire Chief
NFCA President

Rivada Networks

STATEMENT OF RIVADA NETWORKS
September 16, 2010

Rivada Networks strongly supports the urgent call by the Public Safety Alliance to secure legislation (HR5081, S2365 and S3756) that would allocate use and control of the 700Mhz D Block spectrum to the public safety community and provide funding for build out and sustainment, rejecting earlier plans for a public auction of the D Block spectrum.

Public safety officials, including state and local law enforcement, fire departments, emergency medical officials and other first responders have an essential need for expanded access to broadband spectrum for routine operations and for emergency response to catastrophic events. Delivering this additional spectrum capacity to the purpose of ensuring public safety is a national imperative. Allocating the 700Mhz D Block Spectrum will allow for America's first responders to meet current and future communications needs and enable a truly nationwide build-out of interoperable public sector communications networks and protocols, to include rural areas. With the D Block allocated to public safety, our federal, state and local authorities can have access to a broadband network that is flexible and powerful enough to give our first responder community the essential communication tools needed to operate effectively in protecting our nation and its citizens.

Some have argued that 10Mhz is sufficient for public safety. Rivada does not concur with this view. The facts are clear: when communities need critical public safety most urgently, supporting bandwidth and communications infrastructure will be under the most intense strain. Providing the public safety community the communications capacity it needs ensures its ability to save lives during the critical moments of any crisis. The only practical way to ensure that they have adequate capacity is to allocate the entire 20 MHz spectrum to them. During periods when the public safety community is not fully using the network's capacity, it would be able to make capacity dynamically available on a secondary but pre-emptive basis to other governmental and private users. This will also make it possible for public safety users to leverage widely available commercial off-the-shelf products and LTE technology, and it can significantly reduce the burden on taxpayers to pay for ongoing network sustainment costs.

The employees and directors of Rivada Networks have many years of experience dealing with the technical, operational and public policy challenges of public safety communications. Rivada provides emergency communications capabilities to the public sector public safety community at the federal, state and local levels (www.Rivada.com). We see on a first-hand basis each day what access to the D Block as proposed by the Public Safety Alliance can do to strengthen public safety capabilities.

Today, our customers and the nation stand at a fateful intersection regarding this vital public policy debate. Rivada Networks strongly endorses the work of the Public Safety Alliance to help forge a national consensus to allocate the D Block to public safety.

Sincerely,

Declan J. Ganley Chairman & CEO	**Gen. Richard B. Myers (USAF Ret.)** Member of the Board	**The Hon Michael Jackson** Member of the Board	**Adm. James Loy (USCG Ret.)** Member of the Board

April 25, 2011

The Honorable Barbara A. Mikulski
United States Senator
509 Hart Senate Office Building
Washington, D. C. 20510

Dear Senator Mikulski:

As Chief of the Rockville City Police Department, I am writing to advise you of my strong support of the *Public Safety Spectrum and Wireless Innovation Act (S.28),* sponsored by Senator Jay Rockefeller (D-WV) and *Broadband for First Responders Act* (H.R. 607), sponsored by Representatives Peter King and Bennie Thompson. The legislation will allocate D-Block spectrum to public safety for the development of a nationwide interoperable public safety broadband network and designate significant funds to build out and operate the nationwide network.

Law enforcement and public safety must have a minimum of 20 MHz of broadband spectrum to meet current and future needs and must have access to new technologies to perform increasingly complex duties. These technologies must have adequate and dedicated spectrum that is managed and controlled by public safety to ensure that they will be more secure and reliable than commercial systems. The D-block allocation and funding is essential if we are to meet the critical needs of our nation's law enforcement and public safety community.

I am proud to support S.28/H.R. 607, and I urge you to support our efforts as well.

Yours truly,

T. N. Treschuk
Chief of Police

Yucel Ors
APCO International
Director of Legislative and Government Relations

Re: Support of the PSA's D-Block reallocation and funding for Public Safety broadband networks nationally

Dear Mr. Ors,

As you know my firm has long supported the PSA's efforts to acquire additional radio frequency spectrum and funding for public safety broadband networks nationally. We are honored that APCO has leveraged our experience to provide valuable technical and operational information to your team and the PSA. We have successfully debated the FCC's technical experts and when asked, provided critical information to Legislators and members of the Administration. Recent changes in positions on the Hill and The Administration are as a result of your steadfast positioning, the PSA's extraordinary influence and our tireless input to the process. We are proud to work with you, your organization and the PSA and we are committed to continuing our support until we reach a successful conclusion. Rest assured that we will not falter in our commitment to APCO and the PSA. Please continue to call when needed and we will continue to be there for one of America's most valuable natural resources; our First Responders.

Respectfully submitted,

Robert LeGrande, II

November 19, 2010

The Honorable Marco Rubio
Senator-Elect
United States Senate
Washington, D.C. 20510

Dear Senator-Elect Rubio,

USA Software, Inc. supports the allocation of the D Block to public safety and the establishment of a regulatory process and structure to construct a nationwide, interoperable mobile wireless broadband network. The move will improve our nation's homeland security and provide first responders with new voice, video and data communications technologies that are urgently needed. Senate Commerce Committee Chairman John "Jay" Rockefeller, IV of West Virginia recently introduced legislation, **S. 3756: The Public Safety Spectrum and Wireless Innovation Act of 2010**, which provides the basis for implementing this unmet 9/11 Commission recommendation. We would ask that you to consider supporting this legislation.

USA Software, Inc. provides Mobile Data solutions to numerous clients throughout the Southeast United States. Some of the more frequent concerns raised by our customers relating to the current wireless technologies is speed, quality of the connection and, in our rural areas, the simple availability of a wireless network. Our country's local, State, Tribal and Federal first responders, including law enforcement, fire, medical and emergency professionals, must have access to the most modern and reliable wireless broadband technologies to communicate with each other and with federal officials across various agencies and jurisdictions during emergencies. The ability for public safety to have seamless nationwide roaming capability on a wireless broadband network that is hardened to public safety requirements is both achievable and essential for public safety to meet its ever increasing responsibilities.

The Federal Communications Commission (FCC) is planning to address this issue again by the disposition of the D Block via auction. We understand the first attempt by the FCC to auction the spectrum failed miserably. Public safety officials, service providers and infrastructure vendors agree that a more effective method would be to allocate the D Block directly to public safety organizations in order to create a national broadband network that would meet the mission critical needs of first responders.

If allocated, this 10 MHz sliver of spectrum known as the D Block will be combined with the current 10 MHz of spectrum already allocated to public safety to create a 20 MHz block necessary to build out a nationwide public safety broadband network. When built, the new network will be able to support a wide range of public safety, government, critical infrastructure and consumer applications, including voice, video and data services. The wireless broadband network will also enable State, local and Tribal governments to provide more cost effective services to their communities, while saving local and State governments millions of dollars in administering programs such as reading water meters and deploying smart grid technologies. The envisioned public/private partnership will also provide much needed public safety service, as well as commercial broadband service, to rural America.

Corporate Headquarters
9900 Stirling Road, Suite 302 ■ Cooper City, Florida 33024
Telephone: (954) 436-3911 Fax: (954) 431-2641 eMail: sales@usa-software.com Web: www.usa-software.com

One of the top recommendations of the "9/11 Commission Report" was for Congress to "support pending legislation which provides for the expedited and increased assignment of radio spectrum for public safety purposes." We believe Congress must quickly pass legislation to allocate the D Block spectrum to public safety, first proposed in bipartisan legislation introduced by Congressman Peter King (R-NY) and Congresswoman Yvette Clarke (D-NY) as **H.R. 5081: Broadband for First Responders Act of 2010.** The legislation must also provide an annually recurring and dedicated funding source to build and maintain the nationwide public safety wireless broadband network. Senator Rockefeller's bill, S. 3756, which builds upon H.R. 5081, as well as **S. 3625: The First Responders Protection Act of 2010,** as introduced by Senate Homeland Security Committee Chairman Senator Joe Lieberman and former Senate Commerce Chairman John McCain, provides the framework to create a world-class nationwide interoperable public safety broadband network by aligning three crucial components for the welfare of emergency first responders: spectrum, infrastructure and funding.

Our nation cannot afford to miss this one-time-only opportunity to help public safety. We call on Congress pass legislation which will support our first responders who put their lives on the line every day to protect and serve their communities.

Sincerely,

F.A. "Woody" Spencer, Jr.
President/CEO

Re: Support for D Block Spectrum to Public Safety Community

Dear Congressman Dingell:

The Western Wayne County Association of Chiefs of Polices is an organization of 18 Police departments, and other law enforcement agencies that are responsible for protecting over one million Michigan residents.

For the safety of our citizens and to protect critical businesses in the Southeast Michigan area, we urge you to work with your colleagues to support the legislation that will allocate the D Block Spectrum to the public safety community.

We believe that our State, local and Tribal first responders, including law enforcement, fire, medical and emergency professionals, must have access to the most modern and reliable wireless broadband technologies. The additional 10 MHz of spectrum that the D Block provides would be leveraged with 10 MHz of adjacent spectrum that the public safety community has at its disposal in order to create a 20 MHz network that is essential to supporting a wide range of public safety, government, critical infrastructura and consumer needs for voice, video and data services.

Your support for legislation that would allocate D Block for public safety would send a clear message to your colleagues and to members of the Federal Communications Commission. The D block spectrum wireless designation for public safety is needed as an essential element of national security.

We look forward to receiving your commitment of support for D Block legislation. The Western Wayne County Association of Chiefs of Police is confident in your leadership.

Sincerely,

Police Chief Ronald Haddad
Dearborn Police Department

ZETRON
MISSION-CRITICAL COMMUNICATION SYSTEMS

September 30, 2010

The Honorable John D. Rockefeller, Chairman
Committee on Commerce, Science and Transportation
United States Senate
Washington, D.C. 20510

Dear Chairman Rockefeller:

I am writing to express Zetron's enthusiastic support for your legislation, S. 3756—the *Public Safety Spectrum and Wireless Innovation Act of 2010*.

As a manufacturer of public safety communications systems for over 30 years, we understand the significant benefits to public health and safety the legislation offers.

It would establish the funding necessary to construct and maintain a nationwide interoperable wireless broadband network. The network is a critical step toward achieving the interoperability public safety agencies and first responders need in order to communicate with each other during disasters and events that span jurisdictions and agencies. It will also strengthen our nation's homeland security and provide first responders with voice, video, and data communications technologies that will improve their ability to protect our communities and save lives.

The *Public Safety Spectrum and Wireless Innovation Act* would:

- Establish a framework for the deployment of a nationwide interoperable wireless broadband network for public safety.
- Allocate 10 MHz of spectrum—the D Block—to public safety.
- Direct the Federal Communications Commission (FCC) to develop the standards necessary to ensure nationwide interoperability and build-out (including in rural areas).
- Direct the FCC to establish standards that allow public safety officials, when not using the network, to lease capacity on a secondary but preemptive basis to non-public safety entities.
- Provide the FCC with incentive auction authority, allowing existing spectrum licensees to relinquish their airwaves in exchange for a portion of the proceeds of the commercial auction of their spectrum. The funds from these auctions, in conjunction with funds from the auction of other spectrum bands and funds earned from leasing the public safety network on a secondary basis, would be used to fund the construction and maintenance of the nationwide interoperable wireless broadband public safety network.

Again, you have our fullest support and encouragement as you seek to pass this legislation.

Best Regards,

Ellen O. O'Hara

APCO INTERNATIONAL

Spectrum Analysis Report

This report contains…

- Chart of the current public safety spectrum holdings.
- Map of 700 / 800 MHz transmitters in the United States
- Table of the number of mixed licenses in the 470-512 MHz Band. This includes public safety and business/industrial.
- Table of the number of narrowband licenses in the 700 MHz Band. NOTE: Many of these licenses are issued at the regional and state level and they could cover a large geographic area.
- Table of the number of mixed licenses in the 800 MHz band. This includes public safety and business/industrial.
- Table of the number of licenses issued in the 4.9 GHz band.

The data for spectrum tables contained in this report was obtained from the FCC web site at http://fjallfoss.fcc.gov/General_Menu_Reports/engineering_search.cfm?accessible=NO.

Public Safety Narrowband Land Mobile Radio (LMR) Spectrum

29 - 50 MHz (VHF Low Band): The spectrum is non contagious and it interleaved with other uses. Total spectrum allocation in the block is 7 MHz.

Frequencies	Amount of Spectrum (MHz)
30.98 - 31.98	1
33.02 - 33.98	0.96
35.02, 35.64, 35.68	0.06
37.02 - 37.42	0.4

Frequencies	Amount of Spectrum (MHz)
37.90 - 37.98	0.08
39.02 - 39.98	0.96
42.02 - 42.94	0.92
43.64, 43.68	0.04

Frequencies	Amount of Spectrum (MHz)
44.62 - 46.58	1.96
47.02 - 47.66	0.64
Total	7.2

150-174 MHz: The spectrum allocation is non-contiguous and it s interleaved with other uses. Total spectrum allocation in the block is 3.8 MHz

Frequencies	Amount of Spectrum (MHz)
150.7750 - 150.8050	0.03
150.9950 - 151.4975	0.5025
152.0075	0.02
153.7400 - 154.47875	0.73875
154.6500 - 156.2400	1.59
157.45	0.02
158.7225 - 159.4725	0.75
163.25	0.01125
166.25	0.01125
170.15	0.01125
170.425	0.006

172.275	0.006
172.375	0.006
173.075	0.006
173.20375	0.006
173.21	0.006

Frequencies	Amount of Spectrum (MHz)
173.2375	0.006
173.2625	0.006
173.2875	0.006
173.3125	0.006
173.3375	0.006
173.3625	0.006
173.39	0.006
173.39625	0.006
Total	3.805

450-470 MHz: The spectrum allocation is non-contiguous and it s interleaved with other uses. Total spectrum allocation is 3.7

Frequencies	Amount of Spectrum (MHz)	Number of Public Safety Licenses	Use
453.0125 - 453.99375	0.98125	16,914	Nationwide
458.0125 - 458.99375	0.98125	15,105	Nationwide
460.0125 - 460.64375	0.63125	7,148	Nationwide
462.9375 - 463.19375	0.25625	1,649	Nationwide (EMS)
465.0125 - 460.64375	0.63125	6,513	Nationwide
467.9375 - 468.19375	0.25625	2,035	Nationwide (EMS)
Total	3.7375	49,364	

470-512 MHz: The spectrum allocation is made up of 6 MHz contiguous blocks and it is interleaved with other licensees including business/industrial. Total spectrum allocation varies by geographic area from 6 MHz to 18 MHz.

6 MHz Spectrum Block	Number of Licenses Issued	Major Metro Areas
470 to 476	1,133	Boston, Chicago, Miami, Los Angeles, New York City, Cleveland, Pittsburgh
476 to 482	376	Chicago, Detroit, New York City, Cleveland
482 to 488	1,133	San Francisco, Los Angeles, Detroit, Boston, Dallas-Fort Worth, New York City
488 to 494	140	San Francisco, Houston, Washington, DC
494 to 500	41	Washington, DC, Pittsburgh
500 to 506	278	Philadelphia, Southern NJ, Northeastern NJ, Nassau County, NY
506 to 512	171	Los Angeles, Philadelphia, Southern NJ

768-775/798-805: The spectrum allocation is contiguous. Total spectrum allocation is 14 MHz (includes 2 MHz for Guard Band).

806-809/851-854 MHz: The spectrum allocation is contiguous. Total spectrum allocation is 6 MHz.

809-815/854-860 MHz: The spectrum allocation is non-contiguous and it s interleaved with other uses. The total spectrum allocation is 3.5 MHz

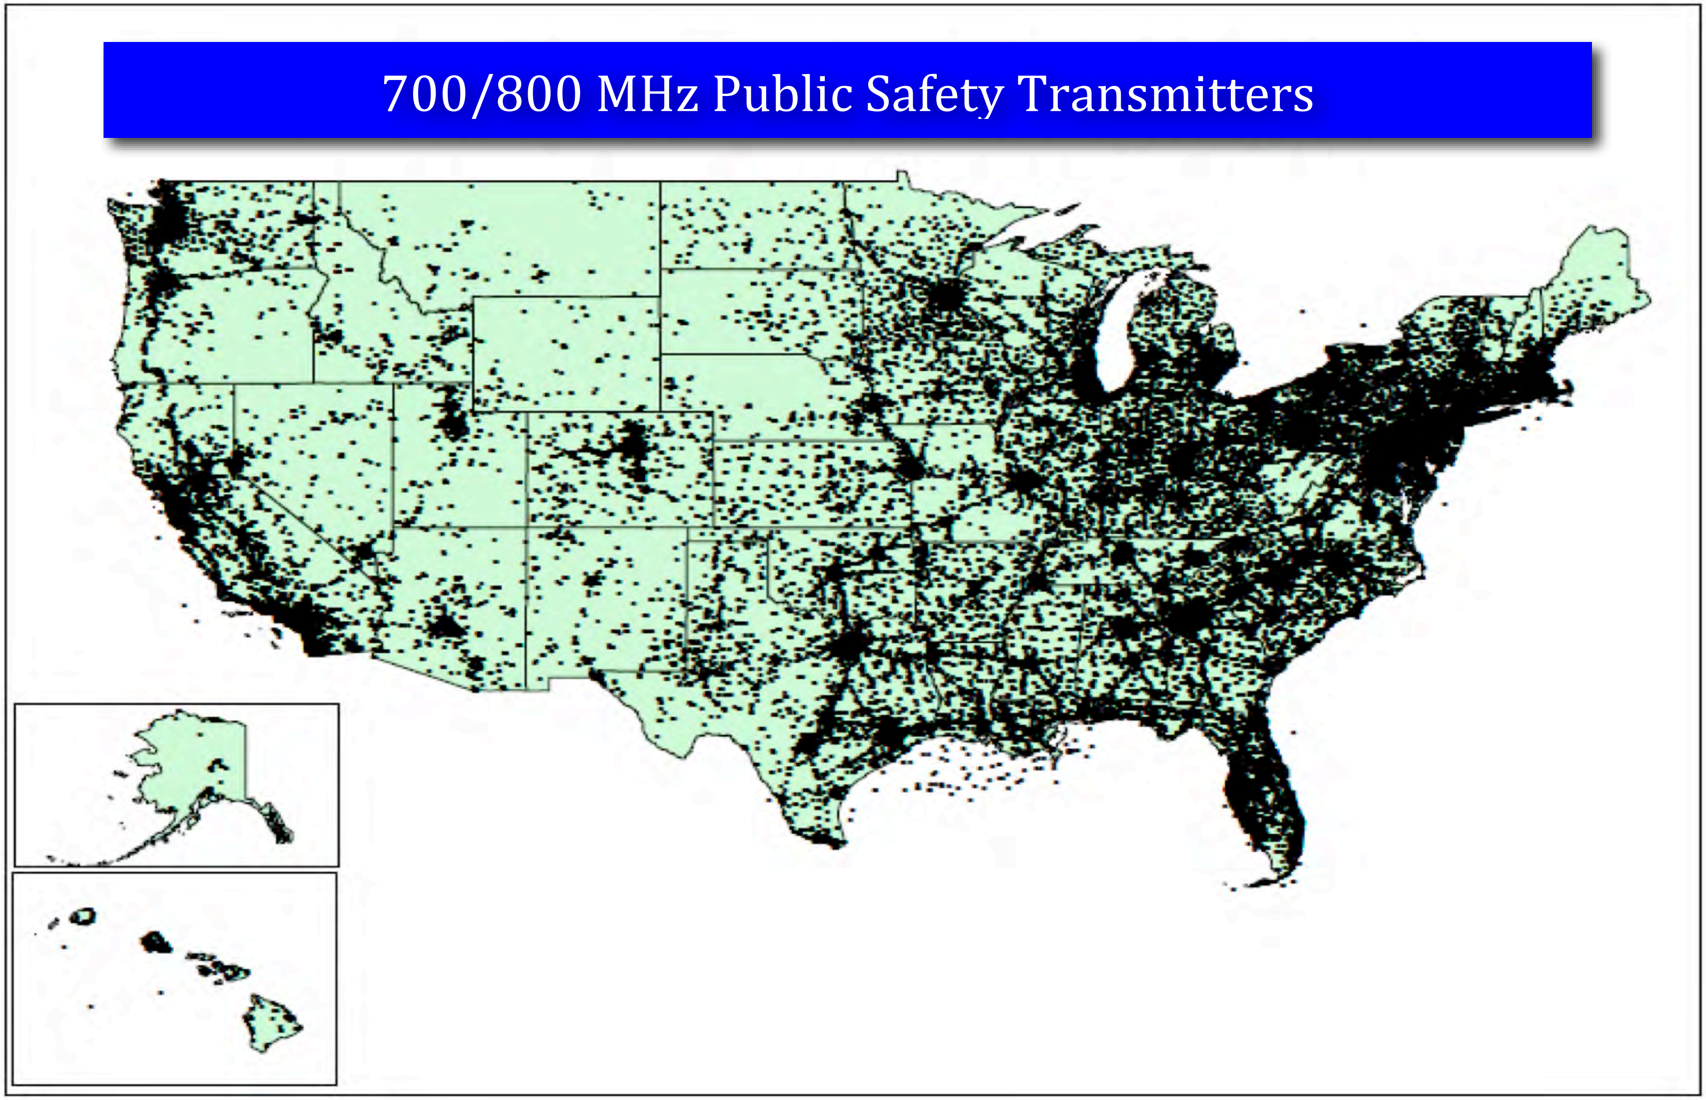
Public Safety Broadband Spectrum

763-768/793-798 MHz: The spectrum allocation is contiguous. The spectrum is designated for deployment of LTE wireless broadband network. Total spectrum allocation is 10 MHz.

4940-4990 GHz: The spectrum allocation is contiguous. The propagation characteristic of the spectrum block limits the use of the spectrum to either hot spot or local area broadband networks, mesh networks, or microwave services. Total spectrum allocation is 50 MHz.

NOTES

- *The 470-512 MHz (a.k.a. T-band) is shared with business/industrial licensees*
- *470-512 MHz, 450-470 MHz, and 851-854, 854-860 MHz bands the total allocation includes paired spectrum for mobile/portable operations.*
- *Assignment of channels in 800 MHz band must be in pairs.*



State and local public safety agencies have put up approximately 79,903 towers across to country for 700/800 MHz land mobile radio systems (there are actually lot more towers for UHF and VHF bands that can also be used for broadband, which are not shown in the map). By utilizing existing public safety tower infrastructure and backhaul, including an extensive array of microwave transmitters and fiber optic networks, the cost of deploying a national public safety wireless broadband network will greatly reduced. This infrastructure combined with commercial networks would ensure greater geographic and populations coverage.

Appendix D – FCC Filings

Who Controls the Network?

The reallocation of the D Block to Public Safety involves many issues including funding the network, how much capacity is needed by Public Safety on a daily basis, and how the network can be used to provide broadband services for non-Public Safety use.

It is clear to me that at the core of this debate is the issue of who will actually control the D Block and manage how it is allocated when there is available capacity. The FCC's position is that the D Block should be owned, operated, and managed by commercial network operators that will work in conjunction with Public Safety on an as-needed basis. Access to the commercial network will be on a priority basis for Public Safety, and the FCC seems to believe priority access is sufficient.

The Public Safety side of the debate is that Public Safety should own, operate, and manage the network and where there is capacity; others should be able to use the network with Public Safety being able to take full control of all of the spectrum on an as-needed basis. Those that would be using the D Block and perhaps some of the Public Safety spectrum as well in rural areas would enter into agreements that would predefine their rights of access. They would become customers of Public Safety with a full understanding that Public Safety has complete and pre-emptive rights to all 20 MHz of the spectrum when needed.

Public Safety has said repeatedly that it is more than willing to work with others and enter into public-private partnerships but that it needs full control over the network's daily operations. Rightfully, Public Safety questions the viability of a commercial network operator deciding where and when to grant priority access to Public Safety. This is a valid concern and neither the FCC nor the commercial operators have addressed it to the satisfaction of the Public Safety community, though Public Safety has been outspoken about how its solution would work.

The amount of available spectrum will change based on geographic area, population density, time of day, and the type and scale of incidents in which the Public Safety community is involved. Meanwhile, commercial operators continue to face increased demand for voice, text, data, and video services from their customers and it is well known that during times of major Public Safety activity, e.g., for a bank robbery or a multi-car collision that can occur any time of day, the demand for broadband and voice services spike for both commercial networks and Public Safety. Expecting a commercial operator to deny service to its regular customer base to satisfy Public Safety's needs will be almost impossible to mandate. Even if mandated by the FCC, the commercial network operator will have to decide whether it agrees with a request for priority access on its network on an incident-by-incident basis.

Commercial networks are run by large companies with multiple layers of management and they have operations centers that may be hundreds or thousands of miles from the incident in question. Public Safety's need for bandwidth is immediate and cannot be pre-planned. Having to request priority access and have it granted on an incident-by-incident basis is not a practical solution. Delays in providing the bandwidth could hamper personnel at the incident. On the other hand, I don't believe commercial network operators would agree to Public Safety being able to grant itself priority access without regard to how congested the commercial network traffic may be. The units in the field that request priority service would be competing with commercial customer requests for service, so it does not appear that there would ever be true “right now” Public Safety priority access to commercial networks. The FCC’s other answer is to pre-stage additional cell capacity mounted on vehicles that can be deployed to an incident when needed. This, too, is unrealistic except for long-term incidents of major proportion such as hurricanes, floods, fires, and the like.

Therefore, the Public Safety community has presented its own idea for priority network management, which is to reverse the process of who has control. Instead of having to contact the commercial network operator or work with it on gaining priority access at some future point in time (time is critical, especially in the early stages of an incident), control over the network would be given to the Public Safety network operator and would be managed in real time. This would provide Public Safety with the assurances that it would have full, pre-emptive priority over all of the spectrum on an as-needed basis.

I believe that commercial users, knowing the circumstances of their network usage ahead of time, would sign up for service and work with Public Safety. I also believe that Public Safety will be cognizant of commercial users’ needs and would take only what additional spectrum is needed for an incident, perhaps bumping the commercial customer down to a lower data rate. If the incident grew and new bandwidth was needed, the commercial customer would be bumped down again and not have any access until such time as Public Safety’s demand for broadband services was reduced.

This method will work, and it is especially viable if you consider that Public Safety will not have to work with individual commercial customers and compete with commercial network operators. Rather, it will work with other city, county, and state agencies, rural power companies, perhaps some rural cellular companies, and organizations that want to use the network to provide broadband to commercial customers in rural America for education, medical, and other uses. These types of partnerships can provide access to both the Public Safety community and these other tenants, and reduce Public Safety’s cost of building out the network and day-to-day operations.

The business model for developing this type of network is readily apparent, as is the fact that as the networks are built out, they will provide broadband services to rural customers years ahead of anything under consideration today. A few examples of the types of partners Public Safety could work with are:

- Rural power companies
    - What they want
        - Smart grid access
        - Broadband access
        - Would like to resell broadband to their rural customers
    - What they have to offer
        - High-tension towers for site location
        - Right-of-ways for backhaul systems

        - Trucks in the field that can be used to equip their rural customers for broadband
        - A desire to partner with Public Safety on this network

- Educational institutions
    - What they want
        - To partner for broadband connections to schools and the student community
    - What they have to offer
        - Access to schools and other properties for cell sites
        - Lease agreements

- Other government agencies
    - Need broadband access
        - City power and water companies
        - Other city agencies
        - Suburban county governments
        - Rural county governments
        - State agencies
    - What they have to offer
        - Lease agreements (funding)
        - Additional sites on government-owned properties

- Tribal lands
    - Need broadband access
        - For Tribal Public Safety
        - For Tribal broadband services
    - What they have to offer
        - Lease agreements
        - Tower sites

- Rural medical services
    - What they need
        - Connections to medical facilities
        - Connections to doctors' offices
        - Connections for visiting nurses
    - What they have to offer
        - Lease agreements
        - Access to medical buildings for cell sites

There are many more types of organizations that could be potential partners, but the above list includes enough organizations to make a solid business case for building out the network as envisioned by the FCC: 44,000 cell sites covering 95% of the population.

In most major metro areas, Public Safety will be using all of the spectrum most of the time. In smaller metro areas, suburbs, and rural areas, there should be enough bandwidth available for these other services, again with the caveat that Public Safety will have full control over the network and be able to allocate resources on an ongoing basis. One example might be in a rural area where a power company is using part of the bandwidth for meter reading at 2:00am and there is a major fire. First responders would use more bandwidth during the incident, including some or all of the spectrum normally available for meter reading, until the incident commander can release some bandwidth, at which time it would be reallocated back to the power company.

The results would be almost the same as what is envisioned by the FCC

- Funding to help with the construction and operation of the network
- Sharing of bandwidth when available
- Public/private partnerships

The ONLY difference here is that the Public Safety community would manage the broadband network. The network would be more tightly integrated for Public Safety devices and applications, and during times of need, Public Safety would not have to contact a commercial network operator to request priority access. All of the other aspects of the FCC National Broadband Plan would remain in place, including Public Safety roaming over commercial networks when there are major incidents, but this type of roaming would not be needed on a daily basis and it would fall under the FCC's plan.

I don't believe commercial network operators want to be in a position of having to make their networks available on a priority basis every day in major metro areas, nor do I believe the type of priority access available in the LTE specifications meets the needs of the Public Safety community. There is no guarantee of full pre-emptive priority, nor are there any mechanisms to ensure that during times of elevated demand on both commercial and Public Safety networks, Public Safety will truly have the level of priority it needs to protect and save.

Further, while LTE is a standard, there are several Public Safety application requirements that are different from those of most commercial customers. Commercial and Public Safety networks operate differently and roaming on commercial networks could result in confusion in the field at times when there is enough confusion in trying to handle the incident. Indeed, LTE is the smartest of all broadband technologies to date and there are many different ways to set allowable data rates, handle capacity, and handle traffic overflows. Most commercial network operators configure their networks to serve the greatest number of commercial customers by managing available bandwidth. Even with priority, there is a serious risk that the most important Public Safety users will be shut out of the network. This is simply not acceptable for mission-critical Public Safety communications.

Reallocating the D Block to Public Safety does not impede private/public partnerships nor does it change the fact that commercial customers can be accommodated over the network, but it does mean that Public Safety will be able to earn revenue from such usage. In fact, it does not diminish any aspect of the FCC's vision for Public Safety, it simply changes who has control of the network so Public Safety is guaranteed full access when needed.

This seems like a reasonable modification to the FCC's recommendations though it does prevent the government from collecting auction funds for the D Block. But in the overall scheme of things, even if the funds amount to $3 billion, that is less than one day's growth of our national debt. Reallocating the D Block to Public Safety is the best approach for all of the stakeholders, including the FCC.

FCC White Paper

The Public Safety Nationwide Interoperable Broadband Network: A New Model for Capacity, Performance and Cost

Published June 2010

Andrew M. Seybold
CEO and Principal Consultant
Andrew Seybold, Inc.

Executive Summary

In June 2010, the FCC published its second white paper supporting its recommendations in the National Broadband Plan (NBP) submitted to Congress in March of this year. The first white paper detailed the FCC's ideas related to the cost of building and operating a nationwide public safety Broadband network. I reviewed that document and prepared my own white paper challenging many of the FCC's assumptions and questioning its findings.

This second white paper details the FCC's analysis of the capacity of the 10 MHz of spectrum already assigned to the public safety community and claim that 10 MHz of broadband spectrum (5 MHz by 5 MHz) will be sufficient for most public safety broadband requirements well into the future. The following is my response to the FCC's second report.

In the introduction to the Capacity Paper, one of the authors recaps points made in more detail in the body of the paper:

> *"The Federal Communications Commission ("FCC") has performed a technical analysis of the capacity and performance of the public safety broadband network assuming that the National Broadband Plan recommendations concerning this network are implemented. This analysis includes examining different emergency situations based on actual experiences and as submitted in the record of the National Broadband Plan. This analysis shows:*
>
> 1. *The 10 megahertz of dedicated spectrum allocated to public safety in the 700 MHz band for broadband communications provides more than the required capacity for day-to-day communications and for each of the serious emergency scenarios set forth below.*
> 2. *For the worst emergencies for which public safety must prepare, even access to another 10 megahertz of spectrum would be insufficient. Accordingly, priority access and roaming on the 700 MHz commercial networks is critical to providing adequate capacity in these extreme situations. Moreover, priority roaming is a cost-effective way to improve the resilience of public safety communications, along with its capacity, in a way that a single network cannot provide.*
> 3. *The capacity and efficiency of a public safety broadband network will far exceed the expectations of someone who has only experienced narrowband land mobile radio (LMR). This is because of the system architecture, density of cell sites, density of cell sectors per site, network and spectrum management, and the use of new and emerging technologies.*
> 4. *Public safety can make more capacity available when and where it is needed by using all of its spectrum resources appropriately and effectively, no matter how much spectrum is available (e.g., use the 700 MHz band for mobile devices and other frequency bands for fixed devices)."*

In reviewing the assumptions the FCC used in reaching these conclusions, I take issue with the following:

1. The FCC is trying to equate voice with data traffic information. Voice communications requires far less spectrum per conversation than broadband data services require. Further, the types of data have a huge impact on the amount of bandwidth available and the capacity of the network within a given cell sector.

2. The FCC claims that video data rates of 256 Kbps will provide sufficient video resolution for most public safety video applications. I and many others disagree with this assumption for many of the video feeds that will be employed by public safety.
3. The FCC claims that land mobile radio systems (LMR) are underutilized most of the time. This is not a correct assumption. LMR systems, as used by public safety, do have periods of light usage, but there are many times every week when these systems are supporting voice traffic that is beyond the capacity of both the existing LMR systems and the capabilities of the dispatch centers to keep up with the demand.
4. The FCC believes that roaming onto commercial networks will occur on a sporadic basis. My research shows that having only 10 MHz of spectrum available will result in having to roam on commercial networks in at least the top 100 metropolitan areas on a daily basis, and for long periods of time for each occurrence.
5. The FCC assumes that the public safety community will have access to 60 MHz of broadband spectrum (its own and that operated by commercial networks). This assumption is not based on any current rules that mandate commercial priority roaming or type of priority roaming and assumes that the winner of the D Block at auction will make its spectrum available for use by the public safety entities, yet its current recommended rules for the D Block auction do not require such cooperation between the public and private sector.
6. The FCC based its usage models only on major scenarios spread out over large geographic areas of a city or jurisdiction. There are no assumptions that look at capacity requirements for smaller incidents that occur on a daily basis and are fairly local in nature and, therefore, will have broadband coverage from only one or perhaps two cell sectors.
7. The FCC believes that local ordinances need to be changed to require the installation of inbuilding network cells (femto, pico, or distributed antenna systems). Yet the FCC has no authority to require that local communities actually do update their existing ordinances, nor does it take into account the cost of providing this inbuilding coverage, nor how it is to be integrated into the network.
8. The FCC's discussion of how much spectrum is already available to the public safety community is flawed in a number of ways. It counts the broadband spectrum at 4.9 GHz that provides only local-area coverage and does not penetrate buildings, it includes the 220 MHz band that is presently used in only one area of the United States because of a conflict on the Canadian border, and it does not take into account that existing channelized spectrum cannot be aggregated into spectrum that could be used for broadband because the channels already allocated to public safety are interleaved with channels assigned for other land mobile radio services.
9. The FCC claims that the public safety community's only rationale for requesting that the D Block be reallocated to public safety is so it can build fewer cell sites and therefore a less expensive network. This assumption is wrong, since public safety is planning to make use of the same number of cell sites recommended by the FCC (44,000 nationwide). The additional spectrum being requested is to provide additional capacity for the network.
10. The FCC used the New York City report on bandwidth requirements to support its own position. However, instead of using all of the assumptions provided in that report, it chose to discount the requirements listed for video services and use its own assumptions as to the number of video feeds that would be required and the bandwidth consumption of each connection.
11. The FCC assumes for the purpose of this paper and in its general findings, that a guard band is not needed between the D Block and the public safety spectrum. However, on May 18, 2010, the FCC requested comments from interested parties to provide input on whether or not a

guard band will be needed, even though the assumptions in its white paper are based on a guard band NOT being necessary.

12. The 700 MHz commercial spectrum that was already auctioned and on which networks are in the process of being built did not carry any requirements for priority access for the public safety community. It is unclear to me whether the FCC has the authority to now require these network operators to provide some type of priority roaming with the public safety community.

It is clear that those involved in preparing the FCC white paper on capacity tried to make the results fit the recommendations they already included in their National Broadband Report to Congress. In reality, this capacity study should have been prepared and released prior to their recommendations to Congress. The FCC focused only on major events or incidents and did not run scenarios based on day-to-day operational requirements. These daily incidents will occur in small geographic areas, sometimes within only a one or two block area of a city or within one-quarter or one-half mile of a jurisdiction. In many cases, these areas will only have broadband coverage from one or two cell sectors. Since this is the norm for public safety responses, this should have been the criterion for evaluation of the amount of spectrum required.

The FCC statement that capacity is based on a number of cell sectors per site, times the amount of spectrum available within each sector, divided by the frequency reuse factor, is true and correct. However, its assumption that public safety would build out fewer sites if it had more spectrum available is not correct. In the case of public safety and its planned network, doubling the amount of spectrum it has available will double or more the amount of bandwidth available within each cell sector. Therefore, the assumption that total capacity is based on other factors as well is not correct. The proper calculations should look at a single cell sector, map the bandwidth available within that cell sector, and then calculate the amount of data traffic (data and video) that will be required both inbound and outbound for typical incidents including a building fire, bank robbery, hostage situation, gang fight, and other incidents that occur on a daily basis but in random locations within jurisdictions.

Further, their discussion of cell sectors and capacity assumes that incidents will occur in areas already heavily covered by commercial network operators. This too is a flawed assumption. If we look at New York City as an example, the commercial operators have learned from experience that in the Theatre District, when the shows let out, the demand for voice and data services will peak. The network operators design and build their systems based on this type of demand, primarily in identifiable locations. The reality of the situation is that criminal events, fires, and other emergencies are not predictable by location, and in many instances the demand for public safety services will occur in areas of the jurisdiction that are lightly served by commercial operators, but bandwidth must be available for public safety.

It is my opinion that the authors of the paper were charged with reinforcing the position previously taken by the FCC that the D Block should be auctioned to a commercial operator. Instead, they should have been charged with taking an uncommitted view of the needs of the public safety community and developing a paper based on an understanding of the differences between commercial and public safety networks and requirements. It appears that this FCC white paper was developed for the purpose of further justifying a position it already recommended to Congress in the National Broadband Report. There are many discrepancies in the FCC white paper and a number of assumptions that, while they may be valid for commercial networks, are not valid for a mission-critical public safety broadband network.

The bottom line for me is that the FCC delivered a report that attempts to once again justify its position that 10 MHz of spectrum is sufficient for use by public safety on a daily basis and that during the occasional times when this is not enough, public safety will be able to make use of commercial network operators' spectrum on some as yet undefined type of priority access. Further, the studies referenced in this report look at broadband capacity from a macro level rather than from a cell sector level. The result is a paper that does not address the real-world broadband requirements of the public safety community on a daily basis, though it does meet the FCC's goal of justifying its recommendations already presented to Congress.

Andrew M. Seybold
Note: My full response to the FCC's capacity white paper is below in PDF format.

Comments on the FCC White Paper on Capacity

Section I: Introduction

In this section of the paper, the FCC reiterates its belief that "*creation of incentive-based partnerships with commercial entities*" will provide many advantages for the public safety community. However, the National Broadband Report does not include any information concerning this type of sharing nor does it require the winners of the D Block auction to work with the public safety community. The FCC seems to believe that the winners of the D Block will be willing to work with the public safety community on a joint build-out. If, as the FCC is presently proposing, the D Block is auctioned in 10 licenses, and the licenses are won by various commercial operators or green field operators, the burden placed on the public safety community to obtain agreements with the D Block winners could materially delay the construction of the public safety side of the network.

Further, as detailed below, 10 MHz (5 MHz X 5 MHz) of spectrum does not provide sufficient capacity for daily public safety needs, let alone enough capacity for commercial operators (the D Block). Thus it is unlikely that the winners of the D Block spectrum will be willing to voluntarily encumber a portion of their commercial spectrum. It is our belief that if public safety is restricted to its own 10 MHz of spectrum, it will have to roam onto the D Block or other commercial spectrum on a daily basis in many of the top 100 metro areas (see below). The FCC is basing some of its recommendations on the fact that the LTE technology supports priority access and roaming. However, the method of priority access (next in line for service or ruthless pre-emption) has not been discussed nor has the number of priority access levels been clarified. The FCC appears to be conducting research and reaching its own conclusions AFTER its broadband report was forwarded to Congress. Many of these issues should have been investigated prior to submission of the report. Now each of the FCC white papers, the previous one on network costs and this one on capacity, are viewed by many as reports designed to reinforce the FCC's recommendations after the fact. It is easy to deliver white papers that "prove" a specific, predetermined view.

It is also unclear to this author whether the FCC will be able to convince the existing 700 MHz spectrum winners that even though they won the spectrum at auction, they must now agree to priority roaming for public safety services. If this roaming will occur on a daily basis, as we believe it will, the value of their spectrum will be impacted as will the level of service they will be able to provide to their customers. If, in a given city, one network operator decides to cooperate with public safety while another operator decides not to, the operator that will not have to share its network with public safety will have a marketing advantage. It will be able to use 100% of its spectrum all of the time while the cooperating network operator will not be able to guarantee full access to all of its spectrum during emergency incidents, when, it has been proven time and again, the demand for both public safety and consumer and business usage in a given area all peak to load requirements that cannot be handled by any network operator. If network operators have to share some of their spectrum during these events, both the public safety community and the network operators' customers will suffer loss of service. And if public safety does not have ruthless pre-emption, it will end up, even with priority, competing with the networks' customers for service.

Another of the FCC's assumptions in this paper has to do with its vision "*that coverage and capacity of the public safety broadband network will be supplemented through in-building systems and through provision of deployable cell sites and vehicular relays.*" It does not say where and how many of these deployable cell sites (cells on wheels or COWs) will be stationed, who will own them, who will pay for them, and how they will be deployed. If they are staged in only a few areas of the nation, the transport time to an emergency scene could be hours if not days and they would not be available at the start of the incident when capacity will be critical. During a major storm or disaster, these COWs will be a welcome addition to capacity for long-term operations, but many incidents are kept from becoming major incidents by decisive action on the part of first responders in the first few minutes or hours. This is the critical period of time when those in charge of the incident need all of the information about the incident available to them, and when they need to disseminate video and other data to those who are in the field as well as back to the dispatch or command center.

The use of vehicular relays or vehicular repeaters has become standard practice within the first responder community for voice services. It is not clear from the LTE specifications if and when this type of device will be supported. However, the 3GPP standards body has addressed the issue of vehicular relays. Unless there is a demand for these devices, the cost of their deployment will be high, and it is not clear exactly how an LTE broadband network will be able to integrate these types of devices. Unlike traditional voice systems employed by the first responders today, LTE networks control the power levels of the devices in the field, decreasing the transmit power if a device is close to the cell center, and increasing it if the device is out toward the edge of the cell. This method of power control is vital to minimizing interference to and from the various sites as well as to and from field devices. Adding vehicular relays that would be capable of higher power or that will use external antennas could easily unbalance the power management important to the LTE network. Further, it remains unclear whether the devices carried by those in the field will have to include additional radios in order to use these relays. In short, the vehicular relay method of supplementing the coverage and capacity of the public safety systems is proven, but there are a large number of logistical problems associated with this approach on LTE networks.

Section II: Why the Plan Meets Public Safety Capacity Requirements: Baseline Capacity

This portion of the paper starts out with the contention that the public safety community already has 60 MHz of spectrum available for broadband use, and that overall, the allocation of spectrum per user for public safety is now 25 times that of commercial providers. There are a number of statements here to which we take exception. The first concerns the 50 MHz of broadband spectrum at 4.9 GHz that the FCC includes in its figure of 60 MHz available for broadband. While licensed for public safety use, this spectrum is adjacent to the 5.8 GHz Wi-Fi unlicensed band and the characteristics of this band make it unsuitable for any type of wide-area broadband coverage. This is a band that can be used for local-area but NOT wide-area communications, therefore it should not be included in the FCC's broadband-available number. This takes the FCC's 60 MHz available for broadband down to 10 MHz of spectrum presently licensed to public safety in the 700 MHz band.

If we deduct this 50 MHz of local-area spectrum, we end up with public safety allocations of 47.1 MHz including the 24 MHz at 700 MHz. Prior to the release of the 700 MHz spectrum, public safety had operated its systems in a total of 23.1 MHz of spectrum in the 30, 150, 450, and 800 MHz bands, with some use of 470 MHz shared with TV stations in major metropolitan areas, and a small slice of 220 MHz spectrum authorized for use in upstate New York because there is a conflict with Canadian spectrum usage on some of the public safety bands. Of the 23.1 MHz of spectrum that has been allocated to public safety over the last 60 years, all of it is channelized AND the channels are intermingled with other land mobile radio systems. Even if there was enough spectrum in any one of the bands, it could not be aggregated for broadband usage.

That this spectrum has been allocated over a 60-year period, that none of it is contiguous, and that it is spread over six to eight different portions of the spectrum is what led to the lack of interoperability for public safety in the first place. Elsewhere in its paper, the FCC contends that this 23 MHz of spectrum is lightly used most of the time. What it doesn't point out is that many times during every week of the year, there is substantial demand for this spectrum, which results in delayed dispatches and response times. States that have been aggressive in building statewide, interoperable voice networks on the spectrum available to them have found that they do not have the capacity to handle the demand for voice radio traffic. For example, Indiana's statewide wireless public safety communications network is now facing overcrowding issues due to a lack of spectrum,[1] and this is for a statewide system that supports 52,000 registered users.

We also find fault with the number of first responders the FCC claims would need access to the network. Its number cited in a footnote on page 4 of its report states in part, "*public safety: According to the Bureau of Labor Statistics, U.S. Department of Labor, there are 1.1 million police, fire and EMS professionals. This number excludes some first responders, such as volunteer firefighters. For this analysis, we assume 2 million public safety users.*" It does not include volunteer firefighters nor does it count other organizations that will need access to this interoperable spectrum such as federal agencies, and agencies and organizations that take on the status of "first responder" during some types of incidents. For example, an automobile that has hit a telephone pole and has a high-power electric line on top of it requires first responder response from the electric company to disable the power line prior to any rescue attempt by fire and EMS personnel. We believe that the true number of users should be in the 4 to 5 million range.

But even using the FCC's number, what it fails to take into account is that most incidents are local in nature and that there will be a concentration of vehicles and personnel in small geographic areas for long periods of time, all needing access to video and data services. As more units and personnel respond to an incident, there will be an increased need to receive information regarding the incident and their assignments. Today, this information is disseminated primarily using the voice channels assigned to a jurisdiction. However, when the broadband network is in place, much of this information will be shared in a digital format including video transmitted from units already on the scene. This concentration of personnel will also lead to the arrival of the press and a number of citizens who are curious about the incident or whose home or business is part of or adjacent to the incident. This, in turn, will lead to increased network usage both for the public safety network and the commercial networks. If, as we believe, public safety will have more demand for digital services than it has spectrum (based on the 10 MHz currently allocated), there will be a need for public safety to roam onto these already congested commercial networks and, even with priority access, there will be delays and loss of information that could end up causing the additional loss of life and/or property.

We believe that the FCC should not have looked at the network capacity issues from a nationwide or major incident basis where there is access to the network through many different cells sites and cell sectors, but rather within the confines of typical daily incidents that take place in much smaller areas of several city blocks or within one-quarter or one-half a mile in which the number of vehicles and personnel will be concentrated and where broadband coverage will be limited to one or possibly two cell sectors. The FCC's report tries to equate voice and data traffic, and the total number of users for a given incident. However, in practice, much of the voice traffic during these typical incidents is taken off the network voice systems and moved onto channels where units can talk to each other without having

[1] Crisis-comm network nearing capacity http://tribstar.com/local/x1703931790/Crisis-comm-network-nearing-capacity

to use the main network. The incident commander will stay in contact on the main network channel, but teams in the field will be assigned simplex or tactical channels.[2] Therefore, the voice traffic will be spread over many different channels enabling teams to communicate among themselves without interfering with other teams at the same incident. The team commanders will be in direct contact with both their own team and the incident commander.

In the case of the public safety broadband network, all of these teams will have to rely on the total bandwidth provided within a single cell sector or two. According to the FCC's own calculations, the total available bandwidth for a cell sector using 10 MHz of spectrum will be 7.5 Mbps down to devices and 3.25 Mbps for the uplink (from the device to the network).[3] However, this bandwidth is not available in the entire cell sector; the amount of bandwidth will diminish toward the cell edges. The FCC's report states that cell edge data capacity will be an acceptable 256 Kbps and points to the National Public Safety Telecommunications Council (NPTSC) report which states "that a system that supports 256 kb/s per video device throughout the coverage area, including edge of cell, is sufficient for public safety in urban areas (and lower data rates are acceptable in suburban and rural areas)" in support of its position. This report was generated in 2007 and was based on technology that was then available in the market. Since this report was published, there have been many studies that conclude that video data rates of 256 Kbps do not provide the level of resolution that will be needed for various kinds of incidents.

For example, in the case of a hostage situation where a sniper is in place and watching the hostage taker and hostages inside a building through a window, video at 256 Kbps will not provide the level of detail needed by the swat team commander and the incident commander, and several other video feeds will probably be needed simultaneously. A number of commercial companies have demonstrated video over LTE at various levels of resolution and have found that 1.2 Mbps video is required in many cases for both the type of resolution and depth of field necessary to be able to properly assess an incident. Even deferring to the Department of Homeland Security's SAFECOM program, we find that 512 Kbps video may be needed. If we run the FCC's own calculations against the benchmark of 512 Kbps video, we come up short on a cell sector basis. However, using the same numbers but with 20 MHz of spectrum, we can achieve the required 512 Kbps of video service availability for a given cell sector.

Also in this section, the FCC tries to make a case concerning the cost of mobile devices if the D Block is not auctioned to a commercial network operator or green field company. Its contention is that the device costs will be higher because there will not be enough demand to reach quantities necessary to provide devices at reasonable pricing levels. On the surface this may appear to be true, but the fact is that many public safety devices will necessarily differ from commercial devices in a variety of ways. They must be hardened products with bright screens that can be viewed in bright sunlight, they must have greater battery capacity, and they must be built for single-handed use (public safety personnel cannot be required to make use of devices that require the use of both of their hands while involved in an incident). By their very nature, they will cost more to build than typical commercial devices. Enabling these devices to work on the lower portion of the 700 MHz band (on AT&T and Verizon's spectrum) will

[2] Channelized Communications http://andrewseybold.com/1456-channellized-communications

[3] Appendix of FCC white paper on Capacity: "In this Appendix, we analyze public safety use of broadband wireless communications employing a network built in accordance with the FCC Cost Model in 10 megahertz of spectrum in four scenarios depicting various types of emergencies. For each scenario, we calculate the expected value of utilization[3] of the network.[3] We assume for purposes of this analysis an LTE network whose capacity averaged over each sector[3] is 7.5 Mb/s (downlink) and 3.25 Mb/s (uplink). These figures represent average throughput and are in-line with current industry benchmarks"

drive the costs even higher. The D Block devices will cost more, but they will cost more than commercial LTE devices as well.

One thing the FCC did not consider in its argument for cost savings is that if the D Block is auctioned and all of the commercial devices built for the D Block licensee are capable of operating on the public safety spectrum, the odds of hackers making their way onto the public safety spectrum and disrupting mission-critical communications are increased dramatically. However, if the devices are built to support the lower bands on the commercial networks and a combined D Block and public safety band for public safety, the commercial devices deployed on the upper and lower 700 MHz commercial spectrum will not be capable of operating in the public safety spectrum, thus reducing the chance of intentional hacking by those interested in proving they are smart enough, or the criminal element who want to disrupt public safety's ability to communicate during an incident or a terror attack.

In Section II, A. Network Capacity Drivers, the FCC attempts to explain that merely increasing the amount of spectrum available does not necessarily mean an increase in capacity. However, here, as elsewhere in its white paper, the FCC seems to be saying that it does not believe public safety will build out its broadband networks to commercial standards and that public safety is only asking for more spectrum in order to be able to construct networks that have fewer cell sites. Therefore, the additional spectrum is needed for added capacity.

This is the formula used by the FCC:

$$\text{Total capacity} = \frac{(\text{\# of sites}) * (\text{\# of sectors per site}) * (\text{Capacity/MHz}) * (\text{\# of MHz of spectrum})}{\text{Frequency Reuse Factor}}$$

The problem with this formula is that it is based on the total number of sites in a system. As discussed above, we need to be looking at the total amount of available bandwidth on a sector-by-sector basis and not based on a total number of cell sites. If we change the formula to reflect the capacity of a single cell sector, we are left with only two numbers:

1) A cell sector with 10 MHz of spectrum available (5 X 5 MHz) has an average throughput capacity of 7.5 Mbps
2) A cell sector with 20 MHz of spectrum available (10 X 10 MHz) has an average throughput capacity of 15+ Mbps

When planning a public safety broadband system, or for that matter a commercial LTE network, these are the only numbers that have any relevance on a day-to-day basis. During a major disaster that covers a large geographic area, there will be more total system capacity. However, toward the epicenter of the incident, we are back to having to contend with the amount of bandwidth available in each cell sector.

According to the FCC, commercial networks are built out using a high density of cell sites, and this is a true statement. However, the FCC does not mention that when commercial operators calculate cell sector capacity, they build in "headroom," or more precisely, they do not plan on a cell sector being full during normal operation. This type of design allows other customers to come into a cell and not be denied service. Thus in reality, the total bandwidth available for load planning purposes is less than the maximum available bandwidth in each cell sector. The calculations are made by determining projected cell sector loading during times known as "busy hours," or the times when demand for service is highest.

Unlike voice networks where there are specific demand peaks before and after work hours, for example, peak data demand occurs more often during each day.

We do not yet know what the design criteria will be for LTE, but we can look at a DSL build-out to understand the relationships of the numbers. With DSL, the network is designed with a standard ratio of 20:1, which means 3 Mbps of data access is available for twenty subscribers. But for the twenty customers, the network is built for an average of 1 Mbps, which assumes that not all 20 subscribers will be using the network at once. This ratio is different for wireless and may in fact be based on 30, 40 or even 50:1. This is important to know because an incident within a given cell sector will break that model due to the high number of users requesting service at one time. If we use these figures and revisit the numbers the FCC provides in the white paper appendix, we find that the system capacity is vastly different from the capacity numbers shown by the FCC. If we push the capacity per cell sector up to 75% utilization, we end up with a total sector capacity of 5.63 Mbps for a 10 MHz system and 11.25 Mbps for a 20 MHz system. These numbers could be lower and have a huge impact on the total bandwidth available during an incident. Adding another 10 MHz of spectrum will provide public safety with more capacity on a sector-by-sector basis. Again, running the calculations in the FCC's white paper appendix using these numbers produces a very different view of the available cell sector capacity.

Typical commercial networks are built out over time and more cell sites continue to be added where there is increased demand for service for a number of years after the initial construction. Demand for commercial capacity can also be planned for. For example, all of the network operators in New York City have more cell sites located near Times Square than in a comparable area in other parts of the city. This is because of the high volume of customers around Times Square and because they know that before and after Broadway shows or other events, network capacity must be increased in these areas to handle the potential demand for services. Even with all of this planning, it is possible to run out of available spectrum. Recently, AT&T announced it would be deploying Wi-Fi access in the Times Square area to help off-load some of the demand for broadband data services over its network.[4]

When designing a public safety broadband network, it is possible to review crime patterns and plan for areas where more capacity will probably be needed, but you cannot plan for incidents that may occur in areas that are not normally affected by high crime rates. For example, in October of 2006, a private plane crashed into a 50-story apartment building on the Upper East Side of Manhattan[5] where crime rates are not normally high, and in 2009 a US Airways plane landed in the Hudson River[6] where one would not normally think a lot of capacity would be needed.

In both of these incidents, all of the commercial networks were quickly jammed beyond capacity as on-lookers, survivors, and the media descended on the areas. The public safety voice channels were also overloaded, and in both instances there needed to be coordination between multiple agencies including several federal agencies. While airplane crashes are, thankfully, few and far between, these are only two examples of incidents that can and do take place in portions of metro areas where you would not build out as many cell sites as you would in Times Square. In both of these cases, public safety would have eaten through its bandwidth capabilities quickly, but having the additional 10 MHz of spectrum from the D Block would have made a huge difference in the total on-scene capabilities of the various agencies that responded.

[4] http://www.computerworld.com/s/article/9177327/AT_T_adds_Wi_Fi_hot_zone_to_relieve_Times_Square_congestion_
[5] http://www.independent.co.uk/news/world/americas/plane-crashes-into-new-york-apartment-block-419676.html
[6] http://www.cnn.com/2009/US/01/15/new.york.plane.crash/

Designing and building broadband networks is not something where a network is built once and never expanded. However, commercial network operators have a distinct advantage because they pre-plan their network architecture to concentrate more capacity in known areas of congestion. If there is a pre-planned event such as a World Series, Super Bowl, or some other large event, cells on wheels can be pre-installed. In the case of public safety systems, the incident types and locations are not as predictable, so it is imperative that each cell sector be deployed with the maximum possible capacity.

Further on in this section of the white paper, the FCC states:

"Another way to increase capacity is to provide supplemental infrastructure to expand available capacity. There are unique strategies for increasing capacity within buildings, where a substantial amount of cellular network traffic originates. Additional infrastructure, such as distributed antenna systems (DAS) and pico cells, can be installed inside buildings to improve coverage and offload traffic from external cell towers. These approaches decrease strains on the available cell site infrastructure. The NBP recommends that building codes be changed or enacted to enable greater use of these technologies and that FCC rules be developed that enable and facilitate their use. Further, additional outreach by the federal, state and local governments to building and facility owners can assist in ensuring that this technology is widely pervasive as 4G networks are deployed.

Capacity can be further expanded by utilizing deployable communications systems, such as next generation cell sites on wheels (a.k.a. "COWs" or "COLTs"[7]*) and vehicular relays, as is frequently done with today's wireless technologies during disasters and major incidents or events. The NBP recommends deployment of these technologies for public safety broadband use, through a program that would help fund caches of equipment throughout the country that can be rapidly deployed to the site of any major disaster."*

I do not believe that the FCC or the federal government has the authority to require changes to local ordinances that would require homeowners, apartment building owners, and office building owners to install distributed antenna systems and picocells (or femtocells). Further, there is a problem with the FCC's logic in this recommendation. Picocells or femtocells would, in fact, increase the broadband capacity inside a given building, but the data would have to be carried over the building's Internet connection back to the main public safety network center where it would have to be integrated with the main broadband network. If the building picocell or femtocell is using DSL or cable bandwidth (or even a T1 line) for backhaul, the effective capacity increase is limited to the capacity of the backhaul. For example, Starbucks offers free Wi-Fi services that it advertises as 802.11G or up to 56 Mbps. However, since it uses a T1 line for backhaul, the maximum bandwidth available within any Starbucks is the capacity of the T1 line (1.54 Mbps). Moreover, the Internet is NOT a mission-critical network.

The public safety community has been hampered by a lack of inbuilding coverage on its land mobile radio channel systems and for years has been struggling with the issue of inbuilding systems. The public safety community has no authority to require inbuilding coverage and building owners strongly lobby against these costly requirements. The FCC believes that these devices will contribute to the overall capacity of the networks, but did not calculate the cost of their deployment or the ongoing costs of the backhaul required to add them to the network. Therefore it is unrealistic on the part of the FCC to include these devices in its calculations of capacity availability for public safety broadband.

[7] "COW" and "COLT" are common industry terms for Cell On Wheels and Cell On Light Truck.

The most glaring of issues here is that distributed antenna systems (DAS) do not increase capacity, they merely make it available inside buildings that are not covered by external cell sites. The reason distributed antenna systems do not increase capacity is that they require a donor cell. They communicate with an external cell sector, making use of that cell sector's capacity and amplifying the signals inside a building. The use of distributed antenna systems will increase data coverage but will do nothing to increase the amount of data capacity available at an incident.

The idea of using deployable communications systems was discussed earlier in this paper, and their applicability would depend on where they are stored, who maintains them, and how long it takes to transport them to an incident. Further, these deployables will require backhaul to the main network, and with LTE networks, they must be interfaced with the network so they can become part of the system. All of this is time consuming and assumes that backhaul data transport is available for this purpose at every scene where deployables might be important in helping with capacity constraints.

Next up is the FCC's recommendation that the public safety community should rely on other transmission technologies such as wireline and fixed wireless technologies for video, which will "*enable public safety to preserve its 700 MHz capacity for mobile broadband communications.*" This recommendation is based on a belief that all video needed at an incident can be delivered by using fixed cameras that are already in place, and that public safety has access to these video feeds. They may have access in some cases, but it is not only the dispatcher who needs to view the camera feed in question, the field incident commander and others at the incident need to view the video as well. The feed from the wired camera will need to be sent over the 700 MHz broadband network if it is to be of value to those at the scene. We also know that many of the video cameras will need to be deployed by personnel at the incident. The only way to transmit this data to others in the field plus the command center will be via the 700 MHz broadband network.

Some of these video feeds will require higher resolution than others. In the case of the sniper on the roof watching a hostage situation unfold through a window, a higher resolution color video stream will be needed. When monitoring congestion on a freeway, a black and white camera with less resolution will suffice. The only way public safety can make use of aerial cameras today is by working with the news media when available. If this video is available, it is high resolution and would need to be rebroadcast over the broadband network to deliver it to those at the incident. It should be noted that the use of cameras in helicopters and airplanes is prohibited by the FCC in both the 700 MHz band and the local-area 4.9 GHz band presently assigned to public safety.

Today's broadband network helicopters transmit video that is of the quality needed by fire and other personnel during these times but 256 Mbps data is not adequate to handle these requirements. Public safety realizes that it will need to manage its bandwidth, but this type of bandwidth management will be much easier on its own network with its own controls. Using a combination of dedicated and commercial shared spectrum at an incident will require expertise and will be a time-consuming process. It would be far better if public safety had to share spectrum only in rare instances rather than on a daily basis, which will be the case with an allocation of only 10 MHz of bandwidth.

Last in this section is the FCC's discussion about how much bandwidth is enough bandwidth. Once again, it missed the point. In the FCC's estimation, there will be times when 10, 20, or even 30 MHz of spectrum will not be enough to meet the demand of the public safety community. This is a true and correct statement. In cases where it does not have sufficient bandwidth available, public safety will be forced to roam onto commercial networks. The question here is if this will occur daily, monthly, or occasionally. The FCC maintains that this need for roaming onto commercial networks will be on an occasional basis, but that assessment is based on bandwidth utilization that considers the total amount of bandwidth available within a system. In fact, the need for more spectrum will arise much more often than our analysis of cell sector capacity shows (see above). The FCC also states that "*Guaranteeing access to these networks will enable the public safety community to have access to substantially more capacity than a dedicated network can provide without vastly more dedicated spectrum than is under consideration. Roaming with priority access will also provide increased reliability and resiliency, especially if any roaming partner utilizes different cell tower sites for all or some of its network."* Yet neither the priority rules nor the type of pre-emption have been discussed with the commercial network operators. The FCC seems comfortable that priority access as defined in the LTE specification will be sufficient. However, this view is based on systems that have not yet been implemented, and using pre-emption that could force public safety to wait in line for access to the bandwidth in a given cell sector, pushing commercial customers to lower speeds but not kicking them off of the network in real time. This means that only a portion of the commercial network operators' spectrum will be available (to be determined by the network operator). Commercial operators will not want to have to explain to their higher paying customers why they could not access their broadband services.

The greatest point of disagreement between the FCC's report and our findings is that the FCC is considering total system bandwidth and we are more concerned about sector bandwidth. At my recent meeting with the FCC's Public Safety and Homeland Security Bureau's technology experts, there were two statements that really brought home to me their lack of understanding when it comes to the needs of the public safety community. The first FCC assumption was that the public safety community wants to model its broadband network after its existing voice networks with fewer high sites and therefore needs the additional spectrum. The other was that during an incident, if a command vehicle was not ideally located it might have to be relocated so it would be covered by a different cell sector with more capacity available. I can just imagine the instructions to the incident commander: "Move the command vehicle one-half mile further from the incident so we can get our video feed." Somehow I don't think this is going to happen. It is the same thing as telling a police officer involved in a shoot-out that he will have to move 20 feet to be able to call for help—and 20 feet from his position behind his car would put him directly in the line of fire. Good luck!

The FCC's final point in this section really tells the whole story about its white paper on capacity. It states, "*As long as sound network management is adhered to, including the provision of adequate funding to construct sufficient cell sites in the network area, the deployment of cutting-edge technology in each cell site, and the use of supplemental tools to increase capacity, network capacity for public safety communications will be significant in 10 megahertz of dedicated capacity."* Any time a statement starts out with "as long as" and then adds conditions on top of conditions, you can be assured that it won't end up being reality. And please note that the FCC used the word *significant* and not "sufficient" in this statement. Not only is the FCC hedging its bets and providing a report after the National Broadband Report was issued, it is carefully making sure that the wording is such that when it is proven wrong, it will be able to hide behind statements such as this one. But by then the damage will have been done.

Section II: B. Public Safety Communications Today

This section starts off with the following statement:

"Unless we are able to get past the mindset that network capacity is synonymous with spectrum, it would be natural to expect that the capacity from this 10 megahertz Block at 700 MHz will be comparable to what public safety has experienced in the past. This is not the case. The public safety LMR networks in use today consume a large amount of spectrum per user. This occurs in part because of legacy network design and technical considerations: public safety networks utilize radio systems with a relatively small number of high site towers and very sensitive radios. This technology and design greatly increases the amount of spectrum needed per user when compared to cellular architectures, which are used for today's commercial communications networks. Further, unlike cellular commercial systems, public safety communications have generally been locally operated, which necessarily results in spectrally inefficient overlapping, independent networks. The NBP recommends that the public safety broadband network utilize a cellular architecture with LTE technology and be deployed in a coherent manner throughout larger non-overlapping geographies. This should result in dramatic increases in spectrum and cost efficiencies, while handling heavier traffic demands than currently exist."

This entire statement, once again, shows the lack of understanding of the real world of public safety communications. Even the proposed public safety broadband network will be comprised of a number of local, metro, regional, and statewide systems. The FCC founded ERIC to assist in making sure that all of these networks are built to the same standards and will interface with each other. It is difficult to understand why the FCC believes that communications networks for public safety, which serve local jurisdictions first, and then coordinate with adjacent jurisdictions, regions, states, and then on a national level, should not be locally operated. There is a significant difference between the types of jurisdictional controls that are needed by local law enforcement, fire, and EMS and the construction of a network or combination of networks.

It is important to decouple the concept of a nationwide broadband interoperable network with the daily needs of local communities. The concept to which the FCC appears to be subscribing seems to suggest that there should be a single 911 answering point located in DC and that all dispatches be made from that center to the entire nation on an area-by-area basis. This, of course, is not a practical solution. What is really needed is to provide for local management of the communications resources of the broadband network with the ability to expand that interface of the local network to regional, state, and even nationwide interoperability on a when-needed basis. Local jurisdictions know more about their own requirements than someone sitting 200 or 2,000 miles away from the agency.

It is also clear from the following statement in this section that the FCC considers broadband systems fully capable of meeting all of the public safety community's voice requirements:

"For example, a recent study of public safety communications in the greater Los Angeles area showed that a shift from today's LMR technology to even a pre-LTE cellular technology could increase capacity per megahertz by a factor of 16. In other words, the study demonstrated that 10 megahertz of capacity on a cellular network would be the equivalent of 160 megahertz on an LMR-type network."

It is interesting that this cited example just happens to come from a paper written by one of the authors of the FCC white paper on capacity.[8] Further, it really underscores the fact that those within the Public Safety Bureau of the FCC, and the commissioners, do not understand the different types of voice

[8] J.M. Peha, "How America's Fragmented Approach to Public Safety Wastes Money and Spectrum," *Telecommunications Policy,* Vol. 31, No. 10-11, 2007, p. 605-618.

communications that are a requirement of the public safety community and not simply a "nice to have" set of capabilities.[9]

There is no doubt that for data services, broadband is more spectrally efficient than channelized communications. However, the FCC failed to point out that many broadband systems do NOT offer voice services. In the CDMA world, Verizon and Sprint, among others, have dedicated data channels for broadband and voice is still run on their 2G networks. Further, in the GSM world, most of the voice traffic is still run over 2G networks and not over the 3G networks, which are primarily reserved for data services. VoIP is, today, less spectrally efficient than 2G commercial voice services or channelized land mobile radio systems.

A blanket statement that more voice calls can fit into less spectrum over broadband is not correct today and will not be correct for the foreseeable future. Further, in order to reach the data speeds required for broadband services, you need far more spectrum than for voice calls. Add to this the fact that today's broadband services and those being planned for tomorrow cannot provide communications when the devices are not within cell coverage, whereas land mobile radio systems do have that capability, and it very quickly becomes clear that the issues indentified in the paper and cited in the FCC report are mixing apples and oranges in order to prove a point that is not based on the realities faced by either the public safety or the commercial wireless community.

The statement by the FCC in this document that says, *"It would be a mistake to design a network based upon the public safety's past experience in using spectrum. Public safety agencies do not have significant incentives to use spectrum efficiently, because, unlike commercial entities, public safety agencies in America do not pay for spectrum"*[10] is confusing at best since the public safety community has already accepted the FCC's recommendation that the entire nationwide system should include 44,000 cell sites. It has never been contemplated by any public safety organization that public safety follow the land mobile radio model. It should be pointed out, once again, that the issue of capacity and capabilities should not be based on the number of cell sites across the nation, but needs to be calculated on a cell sector basis. None of the public safety entities that have been granted waivers by the FCC are planning to skimp on construction of their networks. A review of these proposed networks will show that they are being designed in accordance with standard commercial practices, and take into account the cellular nature of systems used for wireless broadband services. The assumption that the public safety community is attempting to build systems with fewer sites and therefore needs the additional 10 MHz of spectrum is a faulty assumption on the FCC's part.

The issue of how much spectrum is currently available to public safety is overstated by the FCC in some places in this report and stated correctly in others. In one part of the report, the FCC contends that public safety has access to 60 MHz of broadband-capable spectrum at present, but it is counting the 50 MHz of licensed spectrum in the 4.9 GHz range that is totally unsuited for wide-area data services. In yet another part of the report, it states that the public safety community currently has access to only 23 MHz of spectrum for all of its voice services. Not included is the additional information that this spectrum has been assigned over a 60-year period of time, and in many different frequency bands, which is the root cause of the interoperability issue public safety is facing today. Nor does the FCC acknowledge that this 23 MHz of spectrum is not contiguous, which means that today public safety's voice channels are intermingled with those of other land mobile radio users. It also means that even if

[9] http://andrewseybold.com/1456-channellized-communications
[10] Page 8 of the FCC white paper

the spectrum was contiguous, there is not enough of it available in any one band for it to be converted to broadband usage.

It appears that this FCC is determined to repeat the past by providing too little spectrum in one band while stating its willingness to "find" additional spectrum in a different frequency band if needed in the future. Our contention is that public safety has proven, with hard data, that 10 MHz of broadband spectrum (5 X 5) is not sufficient today and it certainly won't meet the needs of the public safety community in the future. If the D Block is not reallocated to public safety, more spectrum will be needed very soon. If that spectrum is located in another band, the public safety community will have to spend even more money adding that spectrum to its broadband network. There will be yet another round of new equipment and new cell site costs, and mobile and handheld devices used on the public safety broadband network will have to be discarded and replaced with new equipment at even higher costs. It makes little sense to build a network and then have to build an additional network that will only perpetuate the FCC administration's earlier mistakes.

Today there is an opportunity to provide additional bandwidth for public safety that is adjacent to its existing 10 MHz of broadband spectrum, the deployment of which would add little to the network and device costs. The D Block, which the FCC has recommended be auctioned to one or more commercial broadband operator, is adjacent to the existing public safety broadband spectrum and this spectrum is needed in order to ensure that public safety, for the first time, has sufficient contiguous spectrum to build a common, nationwide, interoperable broadband network.

Section III: How the Plan Meets Public Safety Capability Needs; Capability Back-Stop

In this section, the FCC continues to try to prove that there is enough capacity within the 10 MHz of previously allocated public safety broadband spectrum. Early in the section, it states that commercial providers will serve 2.7 times the number of users per megahertz than public safety. Here again, the FCC appears to be using numbers for public safety personnel that are too low. It does not acknowledge that during a major incident there are times when off-duty personnel are called back for the incident, nor does it discuss the fact that public safety incidents are usually within confined areas where the number of cell sectors available could be limited to one or two. It does not address the issue of blocked calls or lower data rates that are the result of overloading on the commercial networks that cannot be tolerated in the public safety environment. It should be noted that most of the commercial operators have discontinued their all-you-can-eat data plans in order to help manage their networks more efficiently because, especially in major metropolitan areas, they are experiencing cell sector capacity limitations.

In a footnote to this white paper,[11] the FCC describes how public safety networks are designed for worst-case usage and most of the time they are underutilized. We disagree with this assessment. In

11 For example, as was observed based on usage data from Denver's public safety communications systems, "[m]odern public safety wireless communications systems are generally designed for the worst-case scenario: a large-scale event which requires communication between large numbers of first responders, potentially from diverse agencies. . . . Most of the time, these systems operate at the low end of their designed-for capacity." Joshua Marsh, "Secondary Markets in Non-Federal Public Safety Spectrum," Telecommunications Policy Research Conference (2004). In addition, at its peak, the Minneapolis system handled over two times the number of calls during the I-35W bridge collapse that it would typically expect. During the busy-hour of September 17, 2008, the Harris County Regional Radio System handled almost twice as many PTTs than it would handle on a typical day. See Federal Communications Commission, Emergency Communications during the Minneapolis Bridge Disaster: A Technical Case Study of the Federal Communications Commission's Public Safety and Homeland Security Bureau's Communications Systems Analysis Division at 16-17 (2008) (Minneapolis Bridge Case Study), available at http://www.fcc.gov/pshs/docs/clearinghouse/references/minneapolis-bridge-report.pdf; see also Federal Communications

times of major incidents, the existing voice networks are called upon to operate beyond the capacity they were designed to handle and on Friday and Saturday nights as well as holidays, these networks are already overloaded and dispatch and response delays occur on a regular basis. Long ago, the FCC established guidelines for voice traffic loading on public safety networks.[12] In order to qualify for additional voice spectrum, if any is available, the criteria established by the FCC says that on a single conventional voice channel, the proper public safety loading should be 70 units, and when using trunked radio systems, that loading can be increased to 90 units. Most dispatch systems in the United States have exceeded these loading numbers because voice spectrum is in such short supply. Having broadband capabilities in addition to existing voice networks will reduce some of the overcrowding being experienced on the voice channels, but if there is not enough bandwidth available for day-to-day operations, public safety will experience the same type of overcrowding on its broadband network as it does on its voice networks.

It should be noted that the federal government agencies that are considered to be part of the public safety community include the Secret Service, FBI, and others, and that all of these have networks that are designed along the lines of today's public safety networks. It also should be pointed out that much of this spectrum is lightly used during normal operations but must be available at a moment's notice when needed. When looking at broadband services for all public safety agencies, especially a new broadband network that is intended to serve both day-to-day operations and interoperability requirements, the FCC does not take into account that many types of new applications and services will be developed to take advantage of this network. One example, which will keep police officers on the streets for more hours per shift, will be the ability to complete reports and file them from the field as opposed to the officer making notes with a pen and paper and then having to return to the office to transfer this information into a computer system. It is our contention that just as the iPhone and other smartphones have driven wireless broadband usage up by 5000% over the last two years,[13] the amount of data over public safety networks will also grow substantially as new applications are introduced and as broadband devices are extended from within the vehicles, as they are today, to being worn on the person.

Section III: B. Possible Future Capacity Expansions

The next section of the FCC white paper concerns LTE support of priority access and priority access on different levels. It also states "*Such prioritization schemes have been used successfully in military systems.*" What the FCC fails to disclose in this statement is that many of the military systems use pre-emptive priority—a system where those with high priority can have access to the network immediately and not have to wait for existing users to complete their traffic or to join a network and be assigned only a portion of the bandwidth. Until there are LTE services in commercial operation and agreements with commercial operators are in place, there is no guarantee that the type of priority access envisioned by the FCC will, in fact, be available. Further, as stated before, the FCC is of the belief that the need to employ commercial networks' spectrum on a priority basis will arise only "occasionally" while our findings show that based on cell sector capacity studies, the need to use commercial network spectrum will arise on a daily basis in most metropolitan areas. No matter how many cell sites are developed for

Commission, Emergency Communications During Hurricane Ike: Harris County Regional Radio System: A Technical Case Study by the Federal Communications Commission's Public Safety and Homeland Security Bureau's Communications Systems Analysis Division at 12-13 (2009) (Hurricane Ike Case Study), available at http://www.fcc.gov/pshs/docs/clearinghouse/case-studies/Hurricane-Ike-Harris%20County-120109.pdf.

12 FCC Rules Part 90.269

13 http://blogs.broughturner.com/2010/02/overestimating-mobile-data-growth.html

the public safety system, or the overall capacity of a metro-wide network, the capacity per cell sector is the most important criteria for determining the amount of spectrum required.

The FCC's final point in this section is that "*LTE is in the early stage of technology deployment, and it will continue to progress,"* which is a true statement that should have been qualified with, "However, it will progress based on the stated needs of the commercial network operators that are concerned about issues that affect their own network performance." The FCC also states "*Commercial operators are constantly upgrading their network capabilities to take advantage of greater spectrum and operational efficiencies*." Yet in my discussions with the technologists within the Public Safety and Homeland Security Bureau, these people appear to believe that the public safety network will be built once and not enhanced, and that the number of cell sites will not be increased over time and as demand dictates. This is not a safe assumption, and since the FCC seems to believe that going forward, commercial broadband networks are the model for the public safety broadband network, then the same criteria should apply.

Section III: C. Efficient Use of Public Safety Spectrum

In this section of the white paper, the FCC focuses on the importance of spectrum management and contends that ERIC (the Emergency Response Interoperability Center) will be in a position to help public safety prioritize applications over this network. Again, it includes the roaming portion of its plan to demonstrate the role ERIC can play. However, public safety normally operates on a local basis and each community's needs, and their choice of applications and devices, will be different. The use of this network will be primarily on a local level, thus macro-management from ERIC will not be possible. ERIC's job, as I understand it, is much more confined to the task of making sure that all local, regional, and state networks can interconnect with each other and that devices used in one jurisdiction will work across the entire network when needed. Once again, the FCC seems to believe that federal oversight is all that will be needed to ensure sound network management.

Section III: D. The Role of Video and Future Bandwidth Intensive Applications

I have commented in depth on the differences between what the FCC believes is adequate for video data rates and what will be needed in the real world. Here again, the FCC's attitude is that no matter how much spectrum is available, it will never be enough for all of the video being contemplated for use by public safety. This is an accurate statement, but it does not address the issue of how much video can be employed using 10 MHz of spectrum in a given cell sector versus how much can be employed in the same size cell sector using 20 MHz of spectrum. The answer is more than double. And data rates will be higher in more portions of the cell sector with twice the amount of spectrum.

Public safety today operates in a mode where visual representation of an incident is provided by those on the scene through the use of voice communications. It is envisioned that this will change dramatically when broadband technologies become available. The use of video will add an entirely new dimension to public safety's ability to respond to incidents and to contain incidents that could escalate quickly. Yes, video will have to be managed, and the FCC believes that much of the video should be apart from the wireless broadband network, using wireline and other forms of transporting the video from a camera back to the dispatch center. But delivering video to the dispatch center is only half of the requirement. Once it is received at dispatch, it becomes much more valuable if it is transmitted to those in the field. Likewise, setting up cameras at an incident will provide all who are involved in the incident with the ability to see as well as hear what is happening. Both the dispatch center and incident command personnel will be able to make better, faster decisions about the best course of action. Giving public safety new tools to work with is important, but giving them new tools without the spectrum to use them is not an acceptable solution.

The FCC continues by saying that video resolutions that require 1.2 Mbps are not realistic and therefore should not be used, citing the cost of the network as a basis for this argument and pointing out that in order to support video of this resolution or higher, 2.85 times the number of cell sites would be needed. This statement does not include any data points and is simply presented as a statement of fact. The new FCC management has stressed from the first day of its term that the FCC would be a data driven organization, but in this part of the white paper as well as many others, statements are presented with no supporting data provided.

In reality, high-resolution video will sometimes be required. In the example used previously where a SWAT team sniper is on a rooftop watching a hostage situation unfold through a window, he has a high-resolution scope mounted on his rifle. If the sniper had a camera with high-resolution, it could provide a valuable video feed to the incident commander and others at the scene, and they could better plan their approach to the incident and perhaps save lives in the process. Video bandwidth has been and will continue to be an issue when it comes to how much is needed. However, there will be times when video will be required and if the incident commander deems it necessary for a specific incident, the capacity to provide it must be available.

Section 3: E. The Effect of Interference

This section deals with the issues of adjacent cell interference. The FCC claims that LTE will be more immune from adjacent cell interference than existing LMR systems, and that LTE can be better managed to mitigate next-cell interference issues. This is partially true. LTE handles adjacent cell frequency reuse in a number of ways. However, in a 10 MHz system, each cell will use exactly the same frequency, so minimizing interference through frequency reuse above 1-1 is not possible. This leaves LTE's inherent ability to provide soft frequency reuse. With this method of reuse, the system adjusts the power allocated to certain cell sectors to mitigate intra-cell interference. This is an efficient method of managing cell-to-cell interference, but it means that when there is interference, the amount of power (capacity) at the cell edge is diminished.[14]

During the discussion of the D Block and the public safety spectrum (which are adjacent), the FCC white paper, once again, contradicts itself. On the one hand, the paper claims that no guard band will be needed between the D Block and the public safety spectrum, while in another portion of the paper the FCC states that this is true as long at the two systems do not share the same tower sites.

As mentioned previously, in one of the footnotes to this section, the FCC compares and contrasts interference between LMR radio systems and LTE cell site systems. Since public safety is not planning to build its LTE network based on LMR standards, but rather on the cell standards that are being used in the commercial network world, this comparison is meaningless.[15] The FCC has built much if its case on

[14] http://www.mpirical.com/lms/file.php/1/LTE-Planning-Principles-Part-II.pdf

[15] One important reason that adjacent channel interference can more easily become harmful to LMR systems is that LMR systems are noise limited, meaning that radios must operate well even when they receive very weak signal levels. In contrast to LMR networks, commercial cellular networks are designed to operate despite significant interference. Accordingly, LMR-based networks are inherently more vulnerable to interference, including adjacent-channel interference, than commercial networks. The problem is compounded by differences in the number of cell sites deployed in a given region. The site density of commercial wireless networks is typically much higher than that of public safety LMR networks, as discussed infra. Thus, it is

its belief that the public safety community plans to force fit LTE broadband systems into its existing land mobile radio system designs even though the public safety community has continued to agree with the FCC that the entire system should be comprised of 44,000 cell sites. The FCC has been informed many times that this not correct, yet it continues to include this assumption in its documents to prop up its recommendations to Congress. Once again it must be made clear to the FCC that there is not and never has been such a plan.

Section III: Cost as a Driver for Network Capability
[Editor's Note: This section carries the same number as the previous section]

The main thrust of this section is explained in the first paragraph of the FCC white paper that states in part, "*If public safety uses commercial-scale components in its devices, they will benefit from commercial economies of scale. This is achieved in part by requiring the D Block licensee, and perhaps other 700 MHz licensees, to offer some devices that are also capable of operating in the public safety band. However, if there is no D Block commercial operator, then there will be no ecosystem of D Block commercial devices*." This statement indicates that the FCC does not believe vendors will step up to building chips and infrastructure for the public safety spectrum unless the D Block is auctioned to a commercial network operator, and that if the D Block is allocated to public safety, as it should be, then all of the devices will cost more and there will be little or no incentive for vendors to build these devices.

I have spent a lot of time over the past year addressing this issue, as have others. As of today, there are several chip-level vendors that have already undertaken the task of building chipsets for both the D Block and the public safety broadband network, and others are interested. The device may, in fact, be somewhat more expensive than commercial devices, but as I have stated elsewhere in this report, devices required for many within the public safety community will cost more due to their inherent design requirements: They must be resistant to water and shock, and ruggedized to withstand other typical usage conditions. My conversations with the chip-level vendors indicate that these devices can become available in a number of ways. First, several vendors have said they will build the chipsets and sell them at near commercial pricing if they receive non-recurring engineering funds in the $3-8 million range. This is a onetime expense that can be funded by monies set aside by Congress for these systems, if such funding is forthcoming.

Second, the chip vendors will build chips for this combination of bands and sell them to device vendors at a premium of between $10 and $20 each over commercial chip pricing. In the overall scheme of things, it is far better to have to pay a little extra for these devices than it would be to have to build a second generation of devices with broadband capabilities on multiple bands (the FCC has said if more spectrum is required it will "find it" in another portion of the spectrum). The public safety community does not accept that its special-purpose devices will be made available at the same prices that are paid for smartphones on commercial networks, especially smartphones that are subsidized by multi-year

common for an LMR public safety radio to be far from an LMR cell site, receiving a weak signal that is close to the noise floor and close to a commercial cell site that is transmitting in adjacent spectrum. In this case, interference in the public safety spectrum allocation may be raised in the area directly around the commercial cell site, due to a) the presence of high levels of radiated power in out-of-band emissions; and/or b) intermodulation products that fall within the public safety channel; and/or c) in-band emissions that are too strong to be adequately filtered out by the public safety receiver. Thus, a commercial site using adjacent spectrum can create a coverage hole for LMR radios. This is called a "near-far" interference scenario. The larger the difference in site density between the commercial network and the adjacent public safety network, the greater the probability that this form of harmful interference will occur.

contracts. Our research shows that a wide variety of devices can and will be made available to the public safety sector for pricing in the $500 to $600 range.

The FCC states in this white paper that "*Although not required, NBP deployment costs were calculated using this approach, and the savings were considerable when compared to a stand-alone network dedicated to public safety and does not leverage commercial infrastructure,*" and in the paragraph above this is another statement "*If public safety uses commercial-scale components in its devices, they will benefit from commercial economies of scale. This is achieved in part by requiring the D Block licensee, and perhaps other 700 MHz licensees, to offer some devices that are also capable of operating in the public safety band.*" So on one hand, the FCC white paper is based on device and network pricing that coincides with that of a commercial operator on the D Block. On the other hand, it admits that currently there are no such requirements in the National Broadband Report. Within the same section, the FCC appears to be saying that it will require this type of device cost sharing even by network operators that have already paid for their spectrum and on a different portion of the 700 MHz spectrum.

This raises the issue of the cost differential between a commercial D Block operator and operators that have spectrum in the lower portion of the band. The cost of building a device that provides for operation in the A, B, and/or C Blocks as well as the public safety band will be lower (because of volume) than a device built for use in only the D Block and public safety band. It is hard to imagine that the FCC could mandate what would amount to a price advantage for one network operator over others competing for the same business.

This FCC white paper makes many references to incentive-based partnerships and the cost savings they will offer. However, nowhere in the National Broadband Plan nor this white paper does the FCC say it will require these partnerships, or what type of incentives would be included. The FCC has little if any incentives it can offer commercial network operators without the concurrence of or at the direction of Congress. As far as I am aware, the FCC has not had meetings with commercial network operators to discuss these incentive programs. If and when it does, the results will be very different if the public safety community will be roaming on the commercial networks on a daily basis as opposed to an "occasional" basis as the FCC contends will be the case. Once again, if you review the capacity capabilities of 10 MHz versus 20 MHz of spectrum given the same number of sites, and your calculations are based on cell sector capacity instead of systemwide capacity, the answer to this question will be very different.

Section IV: Conclusion

The Conclusion section of the white paper starts out with this paragraph: *"The NBP's recommendations for the deployment of a nationwide interoperable public safety broadband wireless network were developed over the course of almost a year of intense study, inquiry, analysis and meetings with and input from public safety leaders, communications engineers and industry experts. The result is a plan that will provide public safety with a nationwide, interoperable network that has the capacity for all day-to-day operations and with the innovation of public safety roaming and priority access across the 700 MHz cellular spectrum, surge capacity for emergencies, and even extraordinary contingencies."* And while I am sure this is true, I don't believe the FCC asked either the right questions or asked questions in such a way as to illicit answers that differed from its preconceived notions of what its recommendations should be. I find it difficult to understand how a bureau charged with overseeing Public Safety and Homeland Security communications has put itself at odds with the public safety community from the onset of this important project that should have been approached with a clean slate and open minds.

The FCC has placed too much faith in its own calculations of network capacity and has failed to review demand in terms of cell sector capacity, preferring instead to treat capacity as a networkwide issue. It is also relying on priority access and roaming over commercial networks when priority roaming over LTE is still only a part of the specification and has not been proven to work in the real world. The FCC's white paper is slanted toward its goal of protecting its recommendations to Congress in the National Broadband Report and misses the mark as a fair and complete assessment of the needs of the public safety community.

As stated, it is obvious to me that this white paper was written with the single goal of trying to shore up the FCC's position that the public safety community should be short-changed once again when it comes to the amount of spectrum it needs. In the appendix of this white paper, the FCC cites various large-scale emergency scenarios including one provided in the New York City White Paper on Capacity Usage. Interestingly enough, when discussing this scenario, the FCC discounts the resources those on the front line of these types of incidents call for in favor of its own interpretation of what will be needed. It also ignores the fact that building cell sites that are hardened and include back-up batteries and generators is a problem in a city where most of the cell sites in use are located on building rooftops where fire codes do not permit generators. Building a hardened network in major metro areas will require trade-offs in the number of cells that can be deployed and how many of these can be truly hardened and include back-up power and backhaul redundancy.

Finally, all of the FCC's calculators are based on multiple cell sectors covering a given area. This is not consistent with even the most robust of the existing commercial networks, thus the findings in the FCC white paper are suspect. For more than 60 years, the public safety community has been short-changed when it comes to spectrum allocations. Historically, the FCC has chosen not to commit the amount of spectrum needed by public safety. Now is the first opportunity for this wrong to be righted.

The FCC continues to equate the public safety land mobile radio systems to the new broadband system, but there are many differences between the two. First, over time, the land mobile radio spectrum that was added enabled the public safety community to separate its voice channels onto different parts of the spectrum. By doing so, it gave up the ability to interoperate but was able to use what meager spectrum resources it had been allocated for maximum benefit. For example, in the city and county in which I live, the fire departments for all of the cities and the county make use of the 150 MHz band, using radios capable of all of the channels in use throughout the county as well as channels that are used by Cal Fire and the Forestry Service. This provides a level of interoperability while accommodating as much voice capacity as possible. Meanwhile, the police and sheriff departments use channels in the 450 MHz band. They too have interoperability between the agencies, but in the event of a major incident, the fire and law enforcement agencies cannot effectively communicate with each other.

When implementing a common portion of the spectrum for broadband services, all of these agencies will be sharing the same spectrum and it will not be possible to isolate one from another. Network demand for broadband services will escalate and the result could be network blocking and dropped "calls," which simply cannot be tolerated during even daily incidents. It is imperative that this new network be designed and implemented so there is enough spectrum available for use during multiple daily incidents, and that this bandwidth be sufficient on a sector basis, not on an overall system basis.

The FCC white paper discussion about capacity is based on a view that public safety wants to build fewer cell sites, which is not a correct assumption since public safety has concurred with the FCC recommendation of 44,000 cell sites. It is also based on priority roaming on commercial networks that will only happen on an occasional basis and not on a daily basis as we believe. Then there is the premise that inbuilding network expansion will provide more capacity, which is not true when distributed antenna systems are used, and it is not within the purview of the FCC to mandate such expansion. Further, the cost of deployment was not included in the FCC's white paper on network costs. Finally, the FCC continues to believe that priority roaming over commercial networks will perform as advertised and will provide quick and easy access to commercial network spectrum—even though it has been proven that in times of emergency the demand loads on both the public safety and the commercial networks increase dramatically.

Our Recommendation

It is time for the FCC to revisit its recommendations for the allocation of the D Block that it presented to Congress. If the D Block is auctioned and the public safety community is short-changed once again, it will only be a few years before it will have to return to the FCC and Congress begging for additional spectrum. After more years of delay, perhaps the next FCC will find more spectrum for public safety, but it will be on yet another portion of the spectrum and cause needless increases in both network and device costs. The D Block is ideally suited to being combined with the public safety spectrum and the costs associated with building out 20 MHz of spectrum will be much less than building out two 10 MHz bands located in different portions of the spectrum.

Respectfully submitted,

Andrew M. Seybold

Comments on the FCC White Paper:

Federal Communications Commission
Omnibus Broadband Initiative

A Broadband Network Cost Model:
A Basis for Public Funding Essential to Bringing Nationwide Interoperable Communications to America's First Responders

Published by the Federal Communications Commission April 2010

Andrew M. Seybold
Andrew Seybold, Inc.
April 26, 2010

Executive Summary

The March 2010 FCC National Broadband Plan (NBP) was completed and presented to Congress. A portion of this plan (Chapter 16) was devoted to broadband for the public safety community (Public Safety Broadband Network) for first responders and other public safety personnel. The FCC's recommendations included:

1) *"Creating an administrative system that ensures access to sufficient capacity on a day-to-day and emergency basis;*
2) *Ensuring there is a mechanism in place to promote interoperability and operability of the network; and*
3) *Establishing a funding mechanism to ensure the network is deployed throughout the United States and has necessary coverage, resiliency and redundancy."*

Prior to and after the NBP being presented to Congress, the public safety community as a whole expressed many reservations with this plan. These reservations included concerns about the amount of spectrum that was allocated solely for public safety broadband use based on the FCC's findings that public safety does not need more spectrum for day-to-day operations, the assertion that under this plan, the public safety community would have priority access to all of the spectrum licensed and operated by the 700-MHz commercial operators, and the FCC's projected funding requirements.

In subsequent speeches and presentations,[1] the FCC Chairman and staffers embarked on a campaign to 1) garner support from the public safety community, and 2) defend the recommendations made in the plan. The public safety community was and remains adamant that the NBP as presented does not address the needs of the public safety community for an interoperable nationwide broadband network.[2] It has requested that changes be made to the report and that the members of Congress introduce legislation to correct these deficiencies. Congress has responded with the introduction of H.R.5081[3] on April 20, 2010, and has sent this bill to committee for action.

The FCC's tenor when discussing the NBP report with the public safety community[4] appears to be that if the public safety community wants FCC support for funding the network build-out, it needs to accept the rest of the FCC's recommendations in the NBP report.

The public safety community has responded that the funding is immaterial without enough broadband spectrum to build out the network and has concentrated on pointing out the need for additional spectrum, the willingness of commercial operators to work with public safety, and the fact that even the funding model used by the FCC is flawed.

[3] http://www.opencongress.org/bill/111-h5081/show
[4] http://andrewseybold.com/1518-fcc-a-political-organization

In its latest effort to convince others that its vision for a nationwide public safety broadband network is correct, the FCC has published a white paper[5] that recaps and further explains its rationale for its funding estimates.

Our response takes issue with many of the FCC's assumptions, calculations, and recommendations. For clarity, we have chosen to model this rebuttal on the white paper that was released by the FCC on April 23, 2010, and to discuss these points so they may be easily compared to statements included in the FCC document.

In addition to the issue of funding for construction and maintenance of a nationwide broadband network for the public safety community, there remain a number of other issues including, but not limited to, the amount of bandwidth the FCC believes should be allocated to a standalone public safety network and its assumption that the public safety community will have total, complete priority access to all of the commercial spectrum within the 700-MHz band as it is deployed by the license holders. These issues have been addressed in other articles[6] and publications but have not had as much of an impact on the overall FCC plan as the funding model.

We believe that the FCC white paper is based on flawed network assumptions and design and, therefore, the financial calculations are also flawed. In the body of this paper, we will prove that the entire FCC white paper is based on faulty and unsupported logic.

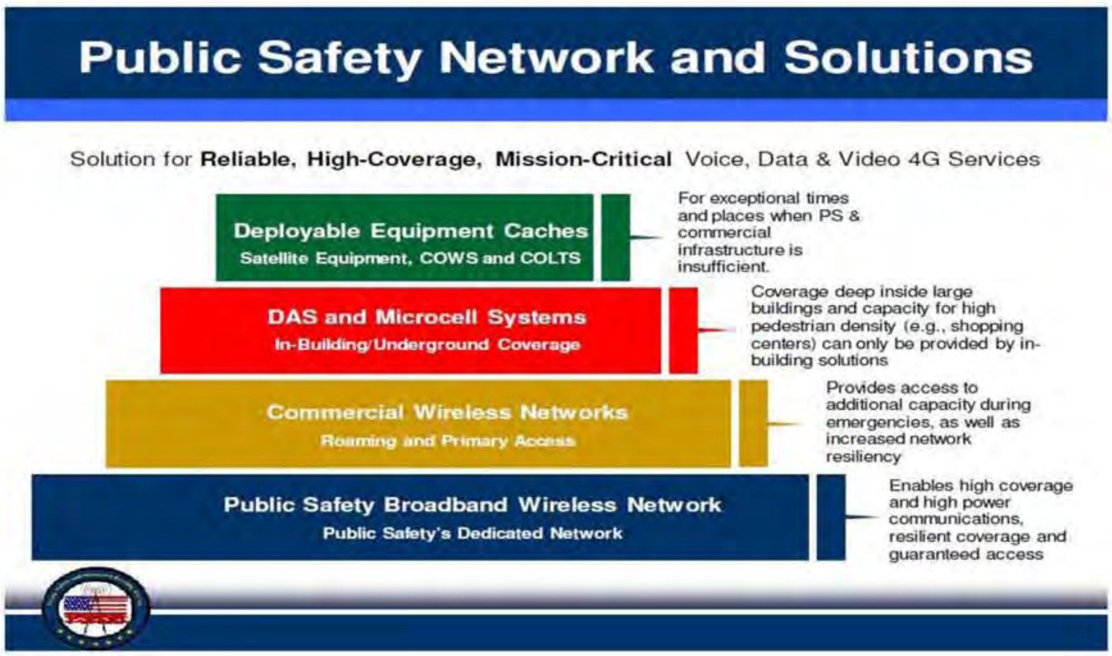
A. Introduction

The Introduction section of the FCC white paper discusses the vision of the NBP to provide "*cutting-edge*" broadband technologies and access to commercial technologies, but at much lower costs. The public safety community specifically, and the wireless community as a whole, have shared this vision for many years. However, if this goal is to become a reality, it will need to be funded appropriately, and will need ongoing support for network operation.

To illustrate this objective, the FCC has included the following diagram and explanation of its multi-pronged approach to solve public safety's communications issues:

Exhibit 2: The Future of Public Safety Broadband Communications



We believe that some false assumptions were made in the crafting of this diagram. First, it appears that the FCC intends for the public safety broadband network to be capable of higher power and to be designed differently from commercial networks within the 700-MHz band. This does not accomplish the stated goal of making use of off-the-shelf commercial technologies, nor does it address the issue of potential interference between public safety and commercial networks. Is the FCC suggesting that the public safety broadband network be another one-off network and not conform to industry standards for broadband networks within the 700-MHz band? If this is really the intent of the FCC, then its assumptions regarding deployment costs are based on this premise and not on providing network architecture in keeping with today's commercial networks or published standards for the technology.

Having a public safety network that runs more power than adjacent commercial systems, with its design based on higher power for both cell sites and devices, has far reaching implications. First is the issue of roaming onto commercial networks with devices that are capable of running higher power than typical commercial devices. Fourth-generation networks control the power output of the mobile device by measuring the signal strength from and to the device and sending signals to the device to adjust the power. If public safety is to make use of higher-power devices, the ability to share common network services with commercial network operators will be compromised, and/or it will mean that each network (public safety and commercial) will need different levels of power management built into them.

Further, if the FCC's intent is to provide higher-power cell sites and devices so fewer cell sites will need to be constructed for the public safety portion of the network, this will also have an adverse effect on the capacity of each cell site, as well as the broadband speeds of these cells, especially at the cell edges. The public safety community has already proven to the FCC that 10 MHz of spectrum will not be sufficient[7] for normal, day-to-day operations, and if the number of cell sites is reduced because higher power is permitted for these sites, the capacity of the overall network will suffer even further. The sensible approach is to design the public safety network in accordance with commercial industry standards for cell density and location. Since it appears as though the FCC financial model was based, in part, on this design criteria, the entire financial model is suspect.

The FCC's diagram shows that public safety will have roaming and primary access on commercial networks that will *"provide additional capacity during emergencies as well as increased network resiliency."* This too is based on faulty assumptions since our calculations[8] and those of others[9] indicate that given the lack of spectrum presently assigned full time to the public safety community, its need to roam onto commercial networks will occur multiple times per day, at least in the top 100 markets. We believe this could easily strain the existing relationship between the public safety community and the commercial license holders. Making sure that public safety roams onto the commercial networks on an *"emergency basis"*-only will require many more cell sites for the public safety network and more broadband spectrum.

During emergencies, commercial networks are typically saturated, which is why public safety needs its own network or, at minimum, a shared network with sufficient spectrum exclusively for public safety. During local emergencies, customers on the commercial networks saturate the network by picking up their cell phones and calling their friends and family members to see if they are safe and to share information and experiences, and every local emergency results in a media response, further saturating the network. Commercial networks fail sooner than public safety networks, so how can commercial networks back up public safety networks?

[7] http://andrewseybold.com/1338-public-safety-broadband
[8] http://andrewseybold.com/1548-fcc-spectrum-plan-based-on-faulty-logic
[9] http://urgentcomm.com/policy_and_law/commentary/fcc-makes-it-worse-20100423/index.html

Next on the chart is the box depicting DAS (Distributed Antenna Systems) and microcell systems for *"in-building and underground coverage."* We agree that this type of equipment will be needed for both public safety and commercial networks. However, we do not see the cost of this equipment included in the FCC's white paper presentation. In metropolitan areas, this type of network deployment can add substantially to overall network deployment costs.

Further, commercial operators that will be deploying small cells, known as femtocells, will require customers to provide their own connection back to the network. At present, this connection can be over DSL or cable modem, and then over the Internet. Therefore, femtocells cannot be considered as mission-critical devices, and their data capacity will be limited by the capacity of the DSL or cable line used to transport the signals back to the network.

The last part of the diagram shows what is called *"deployable"* equipment that is cached at specific locations and deployed on an as-needed basis. This technique has been used by the fire service for years,[10] and has proven effective. However, we believe costs for this equipment are grossly understated and we can find no indication of the inclusion of costs for storage, routine maintenance, or deployment of these caches of equipment.

This one diagram casts doubts on the entire report. A number of the assumptions are not based on real-world understanding or expertise and these assumptions impact all of the budgetary numbers that follow.

The next section of the white paper discusses the costs the FCC believes will be incurred in building and operating the network. It states that costs over the next 10 years will be in the $12-$16 billion range and with state and local governments taking part in some of the funding, the federal government's contribution should only be $6.5 billion for CapEx, which it goes on to justify in the balance of the paper. It further discusses the formation of ERIC, the Emergency Response Interoperability Center that will *"set common standards and practices for the nationwide network."* However, there do not appear to be any costs associated with this government organization to operate ERIC, and we question whether this is even within the purview of the FCC since the Public Safety Spectrum Trust (PSST) is the license holder of the spectrum. According to the FCC's website, the ERIC mission is as follows:

"The mission of the Emergency Response Interoperability Center is to establish a technical and operational framework that will ensure nationwide operability and interoperability in deployment and operation of the 700 MHz public safety broadband wireless network.

ERIC will adopt, implement, and coordinate interoperability regulations, license requirements, grant conditions and technical standards. The Department of Homeland Security and the National Institute of Standards and Technology will contribute to ERIC's functions."

[10] http://www.nifc.gov/communications_radios.htm

While it is not the purpose of this document to discuss the pros and cons of having a federally operated interoperability center, it should be noted here that the public safety community has already developed a set of working criteria for networks[11] that will join in the creation of a nationwide public safety broadband network. It appears from the FCC white paper that one of the primary purposes of ERIC will be to ensure that any public funding will go to organizations and agencies that comply with ERIC requirements.

The final paragraph of the introduction states that:

"The cost model the NBP used to calculate capital expenses and ongoing costs for the network and to inform its recommendation for the public funding program was validated through multiple approaches. First, a detailed radio frequency (RF) model was constructed, and its RF assumptions were validated through a technical analysis that used data acquired from several major commercial service providers, their competitors, and vendors. Costs were based on appropriate comparables, including tariff rates, actual proposals from service providers for similar network builds and operations, and information obtained directly from service providers, equipment vendors, and integrators. Detailed cost scenarios were also developed—and compared with cost scenarios provided by service providers and equipment vendors—to further validate costs."

This set the stage for what those who contributed to the FCC white paper perceive as undisputable facts regarding cost models. However, since the entire network design proposed by the FCC in this paper and in other documents is not based on real-world scenarios, and include the issues we have identified above as well as others, the entire pricing model is suspect. It appears from reading the pages of the paper and discussing them with at least one of the authors, that the cost questions were asked about a design that was already conceived by the FCC. Further, the only information sought from these companies and organizations were answers to specific funding questions rather than a discussion of the fundamental network design and concept.

We believe that if the Commission had asked each of the equipment vendors and integrators it asked about this network, as conceived by the FCC, was practical and whether it would truly meet the needs of the first responder community, the answers and cost estimates would have been very different. The FCC started from a point of believing that 10 MHz of dedicated spectrum will be enough for public safety for the foreseeable future and that most of the networks that will be built will make use of existing commercial cell sites in conjunction with existing public safety sites. The proven reality of the situation is that as envisioned by the FCC, the public safety community will have to make use of commercial spectrum on a daily basis, and this will put a strain on the commercial operators as well as the public safety system.

[11] http://www.npstc.org/documents/700_MHz_BBTF_Final_Report_0090904_v1_1.pdf

In its white paper, the FCC envisions this 10 MHz of spectrum being used not only to carry data and video broadband services but, over time, mission-critical voice and other services. This will compound the issue of not having enough bandwidth on a daily basis, especially in major urban areas. The public safety community, commercial network operators, and equipment vendors (the same ones the FCC relied on for its pricing models below) have already provided the FCC with quantitative data that disputes the FCC's assumptions that 10 MHz of broadband spectrum will be sufficient for the public safety community.[12]

In response to this additional data, the FCC has stated that *IF* it is wrong and more spectrum is needed, it will *"find"* additional frequencies in another portion of the spectrum, which means the FCC will only be compounding the problem of interoperability, network and device complexity, and costs. For decades, past Commissions' failure to allocate sufficient spectrum for public safety communications has resulted in public safety having spectrum resources spread out over many different portions of the spectrum, making interoperability both difficult and expensive to achieve.

B. Assumptions

In the first part of the Assumptions section of its white paper, the Commission outlines what it believes will be a move by public safety to make use of the broadband network for voice, including mission-critical voice services. The evolution as described in the paper is for data and video services first, followed by interoperable mission-critical voice. The report does not make any distinction between the two types of voice services required by the first responder community, neither of which is supported by commercial networks today, and one that is not even on the roadmap for fourth-generation wireless broadband technology. The first type of voice service is one-to-many voice communications, which is a vital element of public safety communications. The second type is the ability for public safety organizations to communicate by voice when they are out of range of a cell site or on an incident that requires one-to-many direct communications.

Because the one-to-many direct communications voice requirement is specific to public safety, and is a core differentiator between commercial wireless voice services and public safety voice services, there is no interest within the commercial wireless community to provide this functionality. Further, the chances of the public safety community having these requirements included in future releases of fourth-generation technology are slim to none. There are a number of technological challenges here and commercial network operators are not interested in providing off-network peer-to-peer or one-to-many voice communications services[13] since they could negatively impact their revenue. Add to this the fact that the command-and-control

[12] http://andrewseybold.com/1548-fcc-spectrum-plan-based-on-faulty-logic
[13] An email to FCC Commissioner McDowell: http://andrewseybold.com/1456-channellized-communications

functions of commercial devices are controlled within the network and not on the device, and it becomes obvious that to include this type of communications capabilities to support 3-4 million customers out of a total customer base of more than 285 million would not make financial sense and will not be included in new versions of the LTE standard developed by the 3GPP.[14]

The next paragraph in this section is also telling since both Verizon and AT&T are already well underway with their 700-MHz construction programs. In fact, Verizon is far ahead in the construction of its network and expects to launch LTE broadband services in the top 30 markets in 2010, covering 100 million POPs and heading for full nationwide roll-out by 2013.[15] Meanwhile, the FCC has failed to act on any of the waivers that have been submitted requesting permission to start building out on the PSST's already licensed spectrum. The FCC's white paper assumes that public safety and commercial networks will be built out together, which is clearly not possible since Verizon is already well on its way toward a nationwide build-out, AT&T is a year behind at most, and the issues with public safety relating to the amount of spectrum and funding have yet to be resolved.

Had these waiver requests been granted in a timely fashion, some of these systems would already be underway in conjunction with commercial operators and we would be within a few months of proving conclusively in actual network operations that the 10 MHz of spectrum allocated to first responders is not sufficient to meet their broadband data demands, and certainly not enough to support data, video, and mission-critical voice services.

This means that savings that might have been possible with a simultaneous build-out of both systems will not happen, at least in the top 100 markets, and this will result in increased costs for the public safety build-out going forward. Even if Congress and the FCC act swiftly with spectrum allocations, new priority access rulemaking, and funding, the window for dual, simultaneous build-outs will have passed.

Commercial operators have no incentive today to design their sites for co-location of public safety systems, or to harden their sites in anticipation that public safety will receive both the approval and the funding to move ahead on a regional basis. There are a number of public safety systems that are in the planning stages but, like their commercial counterparts, they cannot develop network designs that include co-location on sites, and they cannot plan on cost savings from sharing back-end infrastructure and facilities. Thus these systems are being designed to be standalone systems that will meet the stringent requirements for first responder reliability and could be connected to commercial systems in the future.

[14] http://www.3gpp.org/LTE
[15] http://news.vzw.com/news/2010/03/pr2010-03-22c.html

The third paragraph of this section discussed not only the projected coverage of 700-MHz commercial networks, but also the power levels required for the devices to be able to work within these networks. It goes on to state that public safety will be *"able to achieve better coverage and performance than commercial systems by using higher-gain (more powerful) devices with specialized antennas."* This statement, once again, is based on the assumption that commercial and public safety networks will be designed differently and that the public safety network cell sites and devices will be able to run more power to compensate for fewer cell sites. This premise is based on neither sound engineering nor economic criteria.

The FCC appears to assume that the majority of public safety broadband usage will be from within a vehicle where power for devices is not an issue. The reality of the situation is that the public safety community, like the business and consumer communities before them, will require devices that are carried on the person and, therefore, will be limited in power output, antenna design, and battery life. Increasing the power of these devices will greatly reduce their battery life, and could easily cause interference to commercial network cell sites within proximity of the public safety devices.

One of the most troubling of all paragraphs in this section reads:

"Ongoing costs were also calculated on the basis of an incentive-based partnership model. This model assumes that backhaul, core network, managed IP services and ancillary services will be paid through an operating expense charged through a managed service fee. This managed service fee is based on the existing air card managed service fee structure—with the radio access network (RAN) share of the service eliminated, since public safety partners will be using their own spectrum for their primary service."

The commercial wireless community has already drastically changed its business models for broadband pricing. Gone are the days of unlimited broadband services for a fixed monthly fee. This has been replaced with tiered pricing for 50 MB or 5 GB of service per month for laptop systems, and network operators are currently reviewing their options for smartphone broadband usage. Once fourth-generation systems are in place and available to customers, there will be further changes in customer pricing as ways to better manage data usage become necessary. AT&T [16] has reported that only 3% of its iPhone customer's account for more than 40% of its iPhone data traffic on the network, and other operators are finding that they need additional ways in which to manage and control wireless broadband usage. These new pricing discussions have been reported in the press for the past year, yet the FCC seems to be basing its cost estimates for the public safety community on pricing models that were abandoned several years ago.

[16] http://online.wsj.com/article/SB10001424052748704240504574586160553502526.html

Next, the FCC has not factored in the cost of a commercial operator having to split its back-end network to provide for increased security and services for the first responder community, nor has it taken into account the additional hard costs for splitting the back-end services into commercial and mission-critical segments. The commercial operators have expressed a willingness to work closely with the first responder community, but they are not prepared to lose revenue or take a chance on losing commercial customers to provide secure and mission-critical services for public safety.

Commercial operators are in business to make a return on their investment, and they must answer to their stockholders. It was recently reported by Verizon Wireless[17] that its revenue from data services has reached 30% of its total quarterly revenue; the balance was from wireless voice services. As demand for broadband data grows, so too, will the income. However, the FCC certainly cannot expect companies such as Verizon or AT&T to reduce their ability to service their commercial customers and provide them with the best possible broadband experience in order to provide additional capacity that will be needed on a daily basis by the public safety community if its spectrum holdings are limited to 10 MHz of broadband spectrum.

The final paragraph in this section deals with the FCC's determination that the public safety community can make do with 10 MHz of spectrum. One of the reasons provided by the FCC is that there will be roaming on commercial wireless networks. It appears as though the FCC has interpreted the data provided to it in such a way as to believe that this need for use of commercial spectrum will be on an occasional and infrequent basis. The data we have reviewed[18] indicates that if the public safety community must operate within the confines of the 10 MHz presently assigned to it, its encroachment into the public spectrum, on a priority basis, will occur multiple times a day in major metropolitan areas.

The FCC seems to believe that transportable infrastructure will be available to add capacity when there is an incident that requires more bandwidth. It is also relying on in-building supplemental systems to provide resiliency for capacity surges, increased coverage, and increased redundancy. What it is missing is that public safety must respond within minutes and has literally minutes in which to contain a situation that could easily become a major incident. If the communications resources are not available at the start of the incident and first responders have to wait until they can be trucked in, the value of those communications resources is greatly diminished for many incidents.

There appears to be a lack of understanding within the FCC as to how important the first 10, 15, or 20 minutes of an incident are, or how the odds of catching perpetrators or saving buildings decrease only a few hours into the incident. It is obvious to us that the FCC is equating public safety requirements only to events that stretch over multiple days or weeks such at hurricanes or other disasters. Most of the incidents that will require full broadband capacity will require

[17] http://news.vzw.com/investor/20100422.pdf
[18] http://andrewseybold.com/1548-fcc-spectrum-plan-based-on-faulty-logic

that capacity within the first few minutes or hours. Beyond that, for the majority of incidents, there will be fewer requirements, and there will not be the same concentration of first responders on and around the scene.

C. Capital Expenses (CapEx)

This section of the Commission's white paper outlines the total funds it believes are needed for Capital Expenses over a 10-year period. The bottom-line number is $6.5 billion, and in the paper it claims that that figure will provide public safety broadband services for 99% of all Americans. These expenditures are further broken down into $4.0 billion for equipment for commercial towers, $1.5 billion to harden commercial towers, $0.8 billion to equip 3,200 rural towers with public safety broadband spectrum radios, and $0.2 billion for public safety deployable network sites.

Item	Cost	Notes
41,600 Commercially Deployed Non-rural Sites	$4.0 B	Excludes hardening costs. Ethernet over fiber backhaul connectivity to commercial carrier's backhaul Assumes PS RAN (lit) added to 100% of sites (conservative)
Hardening of Existing Commercial Sites	$1.5 B	Assumes 100% of sites need hardening (conservative)
3,200 Rural Sites (includes hardening)	$0.8 B	Assumes EMA, Blend of 25% new and 75% upgraded sites
Deployable Equipment and Development	$0.2 B	
TOTAL CAPEX	**$6.5 B**	

Based on this model, a reasonable year-by-year projection capital expenses is as depicted in Exhibit 4:[11]

There are a number of other charts and graphs in this section that break out in more detail how and when these funds will be needed and in what year of the 10-year project. This budget does not include any costs that might be incurred for roaming by the public safety operator on a commercial network. The use of the word MIGHT in this omission of costs again demonstrates that the Commission believes that 10 MHz of public safety spectrum will be sufficient for its use with only the occasional requirement to roam onto commercial networks. As we have stated, this is one of the items in this report, and in the National Broadband Plan, to which we take exception.

We will comment on the Commission's budgetary Capital Expense figures below, especially when examining the more detailed expenditures outlined in Appendixes B and C, but once again, we believe that none of the assumptions on which this capital expenditure budget result in real-world estimates, nor do they take into account planning and engineering costs, increased site rental fees due to additional antennas required on the cell sites, or any contingency funding. Sound business practice would see an inclusion of contingency funds of between 10% and 20% of the total project, which, in itself, would raise the Commission's budget to between $7.15 and $7.8 billion.

D. Ongoing Costs

In this section of the paper, the Commission discusses its assumptions and the amount of projected ongoing costs. It indicates that by year 10 of the project, the ongoing costs will be $1.3 billion per year broken out as shown in the following chart:

Exhibit 5: Ongoing Network Costs Chart

Item	Cost	Notes
Annual OA&M Including Transport Managed Services Fee	$0.9 B	For 3 M Public Safety Subscribers at $25 per month
Annual RAN Managed Services Fee	$0.2 B	44,800 Sites at $1500 per year for site equipment, OA&M, and $2400 for additional lease cost (this achieves a 99% population coverage)
Additional costs in rural areas (microwave backhaul, additional site lease costs, deployable OpEx)	$0.2 B	Microwave antenna, power and maintenance lease; miscellaneous ongoing costs
TOTAL ONGOING COSTS	**$1.3 B**	

There is a caveat indicated as footnote 12, which states:

"The proposed funding covers network operations. The funding is not intended to cover the operations of the services and applications running on top of that network nor various administrative functions associated with public safety network operations that agencies may incur. These costs which are part of day-to-day operations today which we have assumed will continue to be borne by the local agencies."

Again, since our basic premise is that we do not believe that the underlying assumptions on which this white paper are based are correct, we do not believe the numbers cited are representative of the true ongoing costs of the network, and we will address our concerns later in this document.

E. Cost of Separate Public Safety Network

In this part of the paper, the Commission continues to try to make its case that the cost of its "incentive based" network design described in section B of the paper is $6.3 B but that the cost of an entirely separate network would be $15.7 B. However, it states that "*the cost of the Stand-Alone network described here are less detailed, in part because of the potential range of ongoing costs.*"

The Commission seems to believe that there are only two choices for building out the public safety broadband network. The first choice is its option to essentially combine it with the commercial networks except for some of the radio equipment. The second is to provide a totally separate and standalone network. The FCC does not take into account that between these two extremes are a number of options that can and should be explored. In some parts of the country, the Commission's vision might, in fact, be the best one, in some areas the public safety community will need complete standalone systems, and in other places there could be a combination of the two options offered. For example, it would not be out of the realm of possibility for a core public safety network to be built in a high-use urban area that is not augmented by additional shared sites provided in conjunction with commercial operators. Nor should the possibility of sharing back-end and IP services with commercial operators while maintaining both commercial combined sites and existing public safety sites be ignored.

The Commission is only looking at the two extremes in this paper. It still believes that a total of 44,800 sites will be needed by the public safety community, but states that in its incentive-based partnership it considers the *"marginal cost"* of adding a new radio access network (RAN) for public safety to an existing tower site. Later in this paper, it presents the costs of providing this separate RAN using a common, across-the-board number per site. Reality is quite different.

As commercial network operators build out their own LTE or fourth-generation networks, they will be upgrading their sites in a number of ways, depending on what equipment is already in place, how old the equipment is, and other factors. In some cases, these upgrades will require all new equipment with fiber or microwave backhaul. In others, they will be able to add LTE capabilities to their existing RAN along with new antennas and filtering, and in some cases they will have to find new sites because the sites they presently occupy are saturated and unusable for additional RAN and antennas. Another point that has not been considered in the FCC's white paper is that sites are not always owned by the commercial network operator and can be owned by a third party who rents space to the network operators.

The paper states that *"the differences emerge in the cost per cell site: both CapEx; and OpEx; the costs in zoning and site acquisition, because of many more new cell sites beyond the base required for public safety LMR (Land Mobile Radio) networks; the costs of backhaul from the cell sites; and the costs for the core network."* The Commission has apparently, once again, not considered any options between the two extremes, including sharing backhaul and IP back-end resources with the commercial network operators, acquiring access to sites already developed but owned and managed by third-party tower owners, and other combination solutions. Therefore, we disagree that there is the large cost differentiation detailed in the paper and believe that the real CapEx number lies somewhere between the two extremes.

Exhibit 7: Incentive-Based Partnership vs. Stand-alone Public Safety Network Capital Expenses

Comparison Cost of 44,800 Sites		
	Incentive-Based Partnership	**Stand-Alone Public Safety Network**
Urban Upgraded Site	$95,000	$163,752
Urban New Site	N/A	$223,752
SubUrban Upgraded Site	$95,000	$213,752
SubUrban New Site	N/A	$288,752
Rural Upgraded Site	$216,000	$247,232
SubUrban New Site	$363,000	$394,632
Total CapEx for Sites including Hardening	$6.3 B	$12.6 B
Backhaul - Installation to Core Fiber Ring, Non-Rural Sites	$0	$2.1 B
IP Core Equipment, Network Operations Centers	$0	$1 B
TOTAL CAPEX	**$6.3 B**	**$15.7 B**

The paper continues that in the analysis, *"we considered the complexity and scope of constructing a nationwide public safety network, in which 80% of the 44,800 sites would be new builds."* We disagree with this assumption as well. There are a number of ways to provide access to existing sites for the public safety community, including requirements that any new commercial site constructed be made available, reduced time for permitting if public safety is included in the construction, and other incentives for tower and land owners. Comparing the two extremes in costs in order to justify the Commission's recommendations does not give fair consideration the other available options.

The Commission also neglected to look at the costs to increase the public safety spectrum from 10 to 20 MHz as has been requested and introduced as a pending bill (H.R.5081). The actual costs associated with the addition of 10 MHz of spectrum (the D Block) are minor when compared with the future costs of having to allocate additional broadband spectrum for public safety in yet another portion of the spectrum. The costs for a new spectrum allocation could easily drive the cost of the overall network up by 50% to 75%. The addition of the 10 MHz of adjacent spectrum would only increase the total network costs by 15%-25%.

The Commission's final cost figure for a complete, standalone network including both CapEx and OpEx is $34.4 billion over a 10-year period. Once again, we dispute this number, which the Commission claims is based on documents referenced in the footnotes of the report. Again, the Commission's position is that there are only two options for building and maintaining the public safety broadband network: Its incentive-based network plan or a complete nationwide standalone network owned and operated strictly by the public safety community.

While the public safety community wants and needs its own standalone network that is hardened and secure, there will be trade-offs in different areas of the nation. The series of networks that will eventually be constructed will be made up of a combination of standalone, partially shared, and perhaps even fully shared systems. The Commission's assumption that these networks will be all of one type or another is not correct. Another point worth making is that on the federal government side of law enforcement, there are a number of nationwide, standalone networks that are not shared and are considered to be required because of the needs of the agencies. These networks include the FBI, DEA, Secret Service, and others. Yet the Commission seems to be saying that the state and local public safety community does not have the same needs as these federal agencies. Therefore, public safety should make do with a shared network and less broadband spectrum than it has proven it needs.

In the same section of the paper, the Commission states, "*This lack of scope is compounded if the public safety entity is operating on an LTE network that utilizes spectrum in a band class assigned exclusively for the public safety community. This would be the case if the D block was reallocated to public safety. In that situation, there would be no commercial service provider in LTE Band Class 14 in the 700 MHz band. While technically such a system could be deployed and supported, the costs of the network equipment, most notably the devices, would increase substantially. Without the ability to leverage the economies of scale of a commercial deployment in a band class, there is significantly less market incentive to develop network equipment and devices capable of operating in that band. Therefore, public safety would have to pay significant premiums for equipment and devices under such a scenario."*

This would be a valid point if public safety LTE devices will be built for Band Class 14 only. However, in our conversations with the microchip suppliers, we have determined that all of the basic chips support Class 14, and that while there will need to be changes made to the software masks, some filters, and other components, most of the devices that will be used will be capable of providing service across both the public safety and commercial networks. It is also true that the public safety community is not expecting to be able to purchase broadband devices in their local communications stores. Because of the unique needs of the public safety community, many of the devices will be built specifically to meet public safety's requirements and will, therefore, be priced higher than a $200 smartphone for commercial use. However, the overall cost savings will be substantial and we believe that the industry is willing to work with the public safety community to provide the types of devices it requires at reasonable costs.

Appendix A: Deployable Equipment

This Appendix discusses the inclusion of the deployable caches of equipment that are included in the public funding proposal, which should continue to be a requirement for the overall public safety broadband network. However, it also includes funding for Non-Recurring Engineering (NRE) costs to ensure that specialized chipsets and software will be developed to meet the

needs of the first responder community. This contradicts the statement in Section E above, which states: "*This lack of scope is compounded if the public safety entity is operating on an LTE network that utilizes spectrum in a band class assigned exclusively for the public safety community.*
This would be the case if the D block was reallocated to public safety. In that situation, there would be no commercial service provider in LTE Band Class 14 in the 700 MHz band. While technically such a system could be deployed and supported, the costs of the network equipment, most notably the devices, would increase substantially. Without the ability to leverage the economies of scale of a commercial deployment in a band class, there is significantly less market incentive to develop network equipment and devices capable of operating in that band. Therefore, public safety would have to pay significant premiums for equipment and devices under such a scenario."

The Commission has recognized the need to incent chipset vendors and others to build chipsets and other components capable of providing devices for use in the public safety spectrum, and our discussions with these vendors over the past year indicate that the NRE involved would be the same for developing products only for the 10 MHz of public safety spectrum or for the combination of the D Block and the public safety spectrum. Further, in the overall system costs, these NRE fees will amount to single-digit $millions, and will not have a material impact on the overall cost of the system.

Appendix B: Network Cost Model Assumptions

In this Appendix, the Commission lays out its assumptions that were used to support its costing models and to support its recommendations that the D Block be auctioned in order to provide a commercial network operator that *will "simultaneously build out the LTE Band 14 profile that includes both the D block and public safety spectrum."* However, the proposed D Block spectrum auction rules have been stripped of any requirements for the auction winner to work with the public safety community except to provide priority access.

It is possible, and perhaps likely, that the winner of the D Block auction will decide it can build its own system out quicker and with less expense than by sharing the costs and having to include the hardening required for many of its sites, even if the costs were included in the funding for the public safety network. Any new operator that won the D Block auction would already be several years behind the existing 700-MHz commercial license holders and would, therefore, be incented to move ahead rapidly on its own.

One of the network operators that has expressed interest in bidding on the D Block indicated to us that 10 MHz of spectrum is not enough 700-MHz spectrum for it to be able to compete with the existing license holders, and that if the D Block and public safety systems are built out as separate systems, some spectrum will need to be left fallow between the two systems to prevent interference. This will reduce not only the amount of spectrum available for the D Block winner, it will also reduce the amount of spectrum available for public safety. This, in turn, will have a negative impact for both operators and will reduce both their capacity and their data rates.

The Commission seems to believe that adding another commercial network operator to the mix of existing license holders will put additional pressure on broadband pricing, and that having only two network operators in the band will not provide the same level of competition. This is based on the fact that the two largest network operators have licenses on a nationwide basis. It does not take into account that on a region-by-region or city-by-city basis, there will be three or more broadband providers in the 700-MHz band.

The next point has to do with the subscriber device model and the Commission's assumption that public safety personnel will be able to use larger devices with external antennas and larger batteries, gaining a power advantage over commercial devices. Again, this does not take into account that these devices will also have to be capable of operating on the commercial networks, which are not being designed to accommodate these increased power levels, and some adjustments will have to be made to provide the necessary safeguards if higher-power devices are employed.

Most of the other assumptions in this Appendix have been discussed in detail in other portions of this paper. However, it is worth repeating that the entire Commission plan for the public safety broadband network is based on this statement:

"Priority wireless service on commercial networks, deployables and in-building Supplementation provides for capacity surges, more extensive coverage, and more resiliency thus lowering site requirements on core network."

If required, as we believe they will be on a daily basis in major metro areas, priority wireless services on commercial networks will create both short and long-term issues for both the public safety community and the commercial operators that are trying to keep their commercial customers happy while at the same time accommodating the public safety community. The best way to ensure that public safety's roaming requirements are minimized during normal types of emergency calls is to provide the additional 10 MHz of spectrum known as the D Block.

Again, it should be recognized by the Commission that between the two network extremes discussed in its paper, there are many viable options for public safety and commercial operators working together. If public safety has the spectrum it needs (20 MHz), the level of cooperation will be better on both sides and we believe that more areas of this country will be willing to embrace different types of partnering arrangements when they know they have full and complete access to the bandwidth they need on a daily basis.

At the end of this Appendix is a final statement: *"The model will be refined based on real-life experience in future public funding years."* This means that if the above assumptions are wrong, as we believe they are, then the pricing models are also wrong, and the public safety community could not only be left without enough spectrum for its needs, but with half-completed networks across the United States as well. We have to wonder whether the Commission and Congress are willing to take these risks.

Appendix C: Underlying Equipment and Cost for Capital Expense Assumptions

Here again, a number of the issues we have discussed above are applicable to this Appendix as well. However, we do have some additional observations:

1) Diagrams A and B for Non-Rural site configurations contain detailed lists of equipment and funds for engineering and installation. We find it interesting that these diagrams and their associated pricing are so complete and include equipment down to the most basic levels. It appears as though the authors of this paper were trying to convey a sense of thoroughness in their pricing assumptions. However, their pricing assumptions are based on a flawed system design level as discussed above, and they did not include any contingency funding on a per-site basis. Their assumption appears to be that these numbers would average out across the country. It is not productive in this paper to compare and contrast every item listed in the bills of materials in these diagrams, but we do believe that these estimates are low and that the actual costs will be considerably higher, especially in areas where commercial operators have already built out their networks.
2) Hardening: The assumptions are listed on page 23 of the paper and include generators and associated equipment. However, they do not take into account the fact that many urban cell sites are located on the tops of buildings and it is not possible to add generators due to the weight of the equipment, the storage of flammable liquids, and local ordinances. These sites will have to be hardened in different ways with a different set of cost parameters. Again, we question the costs presented in this section.
3) Microwave System: These prices, while documented, are on a site basis and appear to provide a single path back to either another site or a hub. At the very least, the network hardening should include dual-diversity antennas, and for major sites, a second path to a different entry point within the network.
4) Fiber: There are no cost assumptions listed for fiber, which is also being used for backhaul at many sites, especially within urban areas where microwave (which requires line-of-sight) cannot be deployed. If the assumption is that the public safety system will make use of existing fiber and not need additional fiber connections, we find this to be shortsighted.

Since we believe that the system design and amount of available public safety-only spectrum are based on faulty assumptions, we also believe that all of these cost estimates should be increased to reflect real-world system design criteria.

Appendix D: Capex for Public Safety 700 MHz Builds-Stand-Alone

This section also assumes that each and every network that is to be integrated into the public safety nationwide system will require 100% standalone towers, equipment, backhaul, and back-end services. This would represent the ideal world for public safety—one common network for public safety on a nationwide basis with no equipment or commercial sharing—and it is what the public safety community needs and deserves. However, there is a reality here that there must be compromise if the network is to be underway in a timely and more cost-effective manner.

Conclusions

The Federal Communications Commission seems to be perplexed that the public safety community did not simply endorse the recommendations contained in the National Broadband Plan in Chapter 16. It attempts to make the case that public safety does not need more than 10 MHz of spectrum even though the data provided shows otherwise. It seems to believe that what is best for the nation is to ensure that a third commercial network provider be empowered with its own 10 MHz of spectrum and it has rationalized that public safety can make do with its own 10 MHz of spectrum and sharing, on a priority basis, with all of the commercial operators.

Historically, public safety on a federal, state, and local level has not had to compete with consumers for use of spectrum and has had what little spectrum it controls available to it on a 24 by 7 basis. But now the Commission believes it will not impact public safety communications to have to share spectrum and contend for bandwidth with those who may be viewing streaming video, surfing the web, or playing multiplayer games across the network.

The Commission appears to be baffled that public safety wants 20 MHz of contiguous spectrum and won't settle for a promise that if it needs more than 10 MHz of spectrum it will be supplied at a later date, in yet another portion of the spectrum. It does not seem to comprehend that the reason the public safety community has an interoperability problem in the first place is that over many decades, previous Commissions have allocated small slices of spectrum to public safety and never enough contiguous spectrum to be able to develop and implement interoperability for its voice services.

Now this Commission is about to make the same mistake when it comes to broadband spectrum allocations and leave it to a future Commission to, once again, dole out another sliver of spectrum in yet another portion of the spectrum. At the same time, it is telling the commercial operators that it will find them up to 500 MHz of additional spectrum over the next 10 years and that 300 MHz of this spectrum will be allocated within the next 5 years!

The white paper released on April 23, which is the subject of this paper, is one more way in which the FCC is trying to justify its position and once again short-change the public safety community. It is disappointing that the FCC feels it needs to prove that its plan is the only plan that will work, and by issuing veiled threats, make it clear to the public safety community that if it wants the support of the FCC when it comes to federal funding requests, it needs to endorse the NBP as it has been written.

The white paper does not accomplish its goal. Instead, it makes it clear that the FCC's plan for public safety was, from the start, based on flawed logic and data points that were molded to suit the Commission's beliefs. It was not based on fact, and largely ignored the input provided by the public safety community, commercial network operators, and equipment vendors, all of whom have the experience and knowledge to understand the issues and to prove that 10 MHz of spectrum is not enough for public safety even at the outset, nor is it possible for public safety to share bandwidth with business and consumer customers whose broadband usage peaks at the same time there is maximum demand for bandwidth from the public safety community.

It is even more difficult to understand why, given the opportunity to rectify errors made by previous Commissions at little additional cost to taxpayers, the Commission did not, from the outset, simply propose as part of the National Broadband Report that public safety needed the full 20 MHz of spectrum, and that this would not preclude the public safety community, as well as the commercial community from working together to build a world-class public safety network that would provide, most of the time, the bandwidth they need on a daily basis.

Several times over the last few months, the FCC has indicated that there was no support for the public safety position as advocated by all of the major national public safety organizations and endorsed by major network operators and vendors. Now that there is movement within Congress to address this issue, those within the FCC feel they have to justify their position rather than agree to take a new look at the issues and modify their plan.

Those reading the FCC's white paper who does not understand all of the issues will probably be convinced by all of the charts and graphs that the FCC plan is well thought out and well crafted. They won't understand that the underlying motive is to be able to auction the D Block to enhance competition within the ranks of the commercial network operators. To accomplish that, they will have to short-change the public safety community once again.

Public Safety Broadband Networks	)	

COMMENTS OF NATIONAL BOMB SQUAD COMMANDERS ADVISORY BOARD ON INTEROPERABILITY AND EQUIPMENT CERTIFICATION FOR HAZARDOUS DUTY ROBOTICS SYSTEMS

The National Bomb Squad Commanders Advisory Board ("NBSCAB") hereby submits the following comments in response to the Commission's *Public Notice,* DA 10-884 (May 18, 2009), in the above captioned proceeding, wherein the Commission seeks comment on interoperability and equipment certification for broadband public safety networks. NBSCAB respectfully seeks the Commission consider hazardous duty robotics application in their pending rules making process for the 700 MHz broadband public safety spectrum.

I. INTRODUCTION

NBSCAB, an organization of elected public safety bomb squad commanders representing the bomb squad profession, has the mission to act in a leadership role for the bomb squad community, providing guidance and advice on important issues. The Board promotes initiatives to improve bomb squad tactics, techniques, procedures, training and equipment. The Board provides input and direction toward research and development programs affecting the bomb technician profession. The Board acts as the liaison to the many federal agencies who are involved in issues related to state and local bomb squads. The Board is charged with the responsibility to set guidelines and standards for the bomb squad community through its role as the elected representatives for state and local bomb squads.

II. HAZARDOUS DUTY ROBOTICS IN PUBLIC SAFETY

First responders across the nation face hazardous conditions in the form Improvised Explosive Devices ("IED"), Chemical, Biological, Radiological & Nuclear ("CBRN"), explosive atmospheres, natural disasters, industrial accidents, terrorists, and other hostile criminals. In order to meet each of these types of threats with maximum efficiency and safety, First Responders are increasingly utilizing wireless robotics systems to penetrate hostile environments without exposing personnel to extreme personal risk of physical harm, or death. Robots are utilized for the purposes of visual surveillance, scene assessment, contaminant & volatile atmosphere detection, IED suppression, hostage negotiation, and many other tasks which would have otherwise placed a First Responder at extreme risk.

Robotics control systems, which form an essential point-to-point wireless communications network, are a key aspect of these critical tools, allowing First Responders to maneuver unmanned ground vehicles ("UGV") into hazardous locations from a safe distance away from the threat. These wireless systems are called upon to provide robust connections for the purposes of streaming near-real time video, audio, and telecommand control information, forming a UGV control-loop, with the human operator closing the loop. As threats may occur in any type of terrain, or structure, a

UGV control system must also be robust enough to cope with considerable power losses associated with building penetration and other non-line of sight operating conditions.

III. TECHNICAL REQUIREMENTS

In non-line of sight conditions, an Operator Control Unit ("OCU") video display monitor functions in the same manner as the view through an automobile windshield. The control panel is likewise analogous to the steering wheel and throttle/brake pedals in an automobile. The video signal and the control signals in this type of semi-closed loop control system require RADIO FREQUENCY channel bandwidths 1.25 MHz, up to 6 MHz, depending upon what type of video signal is transported over the air, and what type of RADIO FREQUENCY modulation scheme is utilized. As digital technology continues to mature, these channel bandwidth requirements will continue to decrease. However, today's current state of art video compression and radio frequency equipment continue to demand channel bandwidths in the ranges mentioned above.

The non-line of sight nature of the First Responder threat in which a UGV is typically deployed also demands significant radio frequency channel power to overcome losses created by natural and structural barriers between the mobile UGV and the operator. Stand-off ranges great enough to ensure operator safety contribute to additional propagation losses. Radio frequency channel power loss considerations have traditionally limited industry to utilize channel carrier frequencies under 2.5 GHz, as frequencies above this range incur intolerable losses during normal UGV operations which would include deep penetration into industrial complexes, high-rise buildings, sports arenas, railway tunnels, and other man-made structures.

IV. AUTHORIZATION AND CHANNEL COORDINATION DIFFICULTIES

NBSCAB has identified a nation-wide problem associated with radio frequency station licensing associated with First Responder UGV control equipment. State and local agencies attempting to obtain the required authorizations to operate mobile robotics radio frequency control equipment, pursuant to compliance with *Part 90 Rules,* encounter difficulties associated with channel availability and the unusual nature of the station class. These difficulties regularly result in delays in obtaining operator licensing averaging four to six months, and occasionally up to two years, depending upon the geographical location of the area of operation being requested. These delays, in the opinion of NBSCAB, result in an increased risk to national security, as critical equipment, necessary to defeat threats which include vehicle born IED threats, is unable to be deployed without violating the Commission's Rules. Part of the issue has been determined to be the lack of a regulatory definition, reference of a robotics control station class in the Commission's Rules regulating Public Safety radio frequency stations. Regional and local coordinators have expressed confusion as to what type of equipment is being operated, how it is employed, and why it might require a channel authorization at all, leading to delayed licensing. Additionally, the lack of an official designation for this type of radio frequency station creates channel coordination difficulties during emergencies, particularly wherein multiple agencies may respond to an incident with multiple UGVs. It has been determined that coordination of UGV radio control equipment which is co-located with other First Responder radio frequency equipment, and other UGVs in particular, is essentially non-existent in many locations, creating an additional gap in First Responder safety.

V. INTEROPERABILITY

While NBSCAB recognizes the Commission's commendable and important primary purpose expressed in the *Public Notice* seeking comments on 700 MHz broadband*,* we would respectfully ask the Commission to consider allowing First Responder hazardous duty robotics equipment a presence in the 700 MHz Public Safety spectrum. The channel bandwidth requirements illustrated above indicate a similarity to broadband emissions and this type of equipment may not be authorized for use in much of the spectrum allocated for Public Safety applications. These channel bandwidths greatly exceed those of narrow-band channels dedicated to voice and low-speed data and may not function within the channelization schemes in much of the Public Safety spectrum. Further, Public Safety spectrum which is currently available under *Parts 15* and *90* of the *Rules* for UGV operations either restrict channel power levels to unreliable levels, force UGV operations into shared, uncoordinated bands, or provide carrier frequencies which are susceptible to unsatisfactory propagation characteristics.

The 700 MHz Public Safety spectrum provides an opportunity to populate UGV equipment with wide channels, significant power, up to 5 Watts ERP, effective coordination, and a means to provide a regulatory definition for UGV stations, addressing the difficulties encountered in obtaining channel authorizations. 700 MHz provides superior propagation characteristics, increasing the effectiveness of UGV equipment in hazardous, non-line of sight conditions to any other band of spectrum set-aside for wide-band Public Safety applications. The itinerant nature of UGV emissions, the operational reality that these emissions are limited in geographical area when present due to antenna positioning of between three and fifteen feet above ground level, and the relatively low power of these emissions, 5 Watt maximum, have provided little risk in causing harmful interference to existing broadband networks today. As the equipment is operated directly at an incident scene, with the control unit positioned as forward as possible, while still providing the operator with a safe stand-off range, all civilians are typically evacuated from those hazardous locations and other radio frequency devices are typically limited to tactical communications equipment, the risk of harmful interference from UGV equipment which certified pursuant to the Commission's *Rules* and provided with coordination visibility is limited.

CONCLUSION

Therefore, the Commission should consider the addition of a regulatory definition of UGV equipment to the *Rules* and authorization of UGV stations in the 700 MHz Public Safety Broadband spectrum.

Dear Ms. Dortch:

This letter is to notify you that on March 9, 2010, Northrop Grumman Information Systems ("Northrop Grumman") representatives Edward J. Dempsey, Manager, Wireless and Public Safety Solutions, Ajay Gupta, Engineer, Communications Systems, Thomas S. Afferton, Director of Strategy and Technology, Commercial State and Local Programs, and I, along with William J. Andrle, Jr., Telecom and Spectrum Strategy Vice President of TASC, Inc., participated in a telephone conference with representatives of the Commission's National Broadband Plan, Office of Engineering and Technology, and Public Safety and Homeland Security Bureau being copied on this letter as shown below.

This discussion was at the request of the Commission's staff, to answer their questions regarding the New York City Wireless Network (NYCWiN) citywide mission-critical broadband mobile wireless system for public safety, which was designed and built by Northrop Grumman. The conversation covered the following points:

- Operational details and performance parameters of the NYCWiN system derived from actual public safety operations, and future usage and network loading projections based on these actual results and trends in usage.
- The application of this data to public safety requirements and spectrum needs, now and in the future, for the operation of such a network in the 700 MHz band.

- Based on this actual data and derived analyses, the potential or likelihood that any foreseeable regime of public safety "roaming and priority access" on commercial 700 MHz networks, as suggested by the Commission in recent statements,[1] would not be an adequate substitute for direct public safety access to 20 MHz of spectrum (as proposed by the public safety community in seeking the 700 MHz D Block spectrum) to meet public safety needs for mission-critical grade mobile broadband wireless service.

All of the NYCWiN system data and projections discussed by Northrop Grumman are on record with the Commission in a filing by the City of New York in WT Docket No. 06-150 and PS Docket No. 06-229.[2]

Although this conversation was within the Sunshine Agenda period prior to a scheduled Commission meeting involving some of the subject matter, the Commission has waived the Sunshine prohibition on *ex parte* communication under the Commission's Rules.[3]

If you have any questions regarding this notice, please do not hesitate to contact me.

Sincerely,

cc:

Summary

Creating a nationwide interoperable public safety broadband network is rightfully a key priority of the Commission. The Commission's May 12, 2010, Order granting waivers to twenty one public safety entities to allow for early deployment of statewide or local public safety broadband networks in the 700 MHz public safety broadband spectrum was an important step towards realizing this goal. In these comments, Motorola offers guidance on how the Commission can best nurture these and other pioneering networks through a light-touch regulatory approach based on setting the key requirements for interoperability, encouraging the use of standards-based solutions wherever possible, and otherwise allowing public safety waiver recipients to develop the best networks for public safety's particular needs.

Ensuring interoperability among the many regional networks is essential to the success of providing nationwide public safety broadband services. While providing service to roaming public safety responders is key for all networks, each local and regional public safety broadband network will have different challenges and requirements that will demand at least some level of customization. This flexibility and creativity should not be suppressed with onerous regulations. Motorola recommends that the Commission set only the minimum requirements necessary to ensure interoperability among the public safety broadband networks and otherwise refrain from prescriptive regulatory mandates. This approach will allow public safety networks to develop according to the needs of their users, while also providing an interoperable foundation upon which the nationwide interoperable public safety network can be built.

In these comments, Motorola identifies specific areas and parameters where standards should be established for public safety broadband networks. These standards need not be codified into the rules – Motorola expects that public safety users, vendors and 700 MHz commercial service providers will find the appropriate vehicle to effectuate these types of recommendations without regulation. The Commission's Emergency Response Interoperability Center should monitor and facilitate such efforts as needed.

To provide the best route for an advanced, interoperable, nationwide wireless broadband network that will serve public safety needs in times when emergency communications are needed most, the Commission should support efforts to obtain a reallocation of the D block directly to the public safety community. Without the D block spectrum, public safety users will have insufficient resources to accomplish their missions during times of emergency and may even be prevented from taking advantage of the full benefits of wireless broadband technologies and applications during their day to day use. This will require greater reliance on commercial networks, even for day to day activities, which will increase operational costs for local governments. Moreover, reallocation of the D block would help resolve some of the outstanding technical and operational issues identified by the Commission in the Public Notice, such as those related to roaming, network performance and interference protection.

COMMENTS OF MOTOROLA, INC.

Motorola, Inc. ("Motorola") hereby responds to the request for comments on the necessary technical requirements for public safety broadband networks operating in the 700 MHz band.[1] Motorola strongly supports the efforts of the Federal Communications Commission ("Commission") and its Public Safety and Homeland Security Bureau ("Bureau") to promote the development and construction of interoperable regional public safety broadband networks that collectively contribute toward the goal of a nationwide public safety broadband network.

I. Introduction and Summary.

Creating a nationwide interoperable public safety broadband network is rightfully a key priority of the Commission. As the Commission explained in the National Broadband Plan, "the country has long recognized the potential for broadband technologies to revolutionize emergency response wireless mobile communications. This

[1] Public Safety And Homeland Security Bureau Seeks Comment On Interoperability, Out Of Band Emissions, And Equipment Certification For 700 MHz Public Safety Broadband Networks, PS Docket No. 06-229, *Public Notice*, 25 FCC Rcd 5486 (2010) ("*Interoperability Public Notice*").

technology will give first responders new tools to save American lives."[2] The Commission's May 12, 2010, Order[3] granting waivers to twenty one public safety entities to allow for early deployment of statewide or local public safety broadband networks in the 700 MHz public safety broadband spectrum was an important step towards realizing this potential. In these comments, Motorola offers guidance on how the Commission can best nurture these pioneering networks through a light-touch regulatory approach based on setting the key requirements for interoperability, encouraging the use of standards-based solutions wherever possible, and otherwise allowing public safety waiver recipients to develop the best networks for public safety's particular needs.

Although the vision of a nationwide interoperable public safety communications network goes back much farther, the current proceeding can trace its immediate roots to the 2008 700 MHz auction ("Auction 73"), in which the Commission set forth a 700 MHz band plan that included one 10 MHz paired (5 + 5 MHz) block of public safety broadband spectrum (763-768/793-798 MHz) and one 10 MHz paired (5 + 5 MHz) block of commercial spectrum at the Upper 700 MHz D block (758-763/788-793 MHz) that were to be used together to provide spectrum for public safety broadband services through the creation of a public-private partnership.[4] Under the 700 MHz service rules in place at the time of Auction 73, the D block licensee would be responsible for helping to

fund and develop the nationwide public safety broadband network and would provide to public safety users preemptive and priority access to the D block commercial broadband spectrum during times of emergency. In exchange, the commercial D block licensee and its commercial customers would have access to the public safety broadband spectrum on a secondary basis.

The D block license did not attract a bid above the Commission's reserve price at auction. As Motorola has explained previously, the D block auction failed because commercial entities could not absorb the additional costs of building a commercial system designed to public safety specifications and still be able to charge commercially competitive rates.[5] The costs of meeting the heightened coverage and reliability requirements demanded of a nationwide public safety wireless broadband network for the relatively small number of first responders across the nation made it difficult, if not impossible, to comprehend building a network that was viable based on market competitive service rates.[6]

In the wake of Auction 73 the Commission initiated proceedings to determine how best to move forward with promoting the development of a nationwide public safety wireless broadband network and how the Upper 700 MHz D block spectrum can best facilitate this goal.[7] These issues have yet to be resolved. In the meantime, however, at

least twenty one jurisdictions have indicated that they are ready to begin development of public safety broadband networks now, in advance of final rules for the 700 MHz Public Safety Broadband spectrum and the Upper 700 MHz D block.[8]

The initial requests for waiver were publicly supported by the Public Safety Broadband Licensee ("PSBL") the Public Safety Spectrum Trust ("PSST"),[9] the National Public Safety Telecommunications Council ("NPSTC"),[10] Motorola,[11] and numerous other parties. The PSST also submitted, in an ex parte filing, a report completed by the NPSTC Broadband Task Force ("BBTF"), which addressed recommended conditions for the waiver petitions and proposed other operational and governance structures to help ensure such deployments are interoperable.[12] Most commenters generally supported the recommendations of the NPSTC BBTF Report, including the use of the 3GPP Release 8 ("LTE") protocol as a standard air interface for all public safety wireless broadband networks. On May 12, 2010, the Commission granted the waivers, conditioning its grant on adherence to a limited set of operational and technical requirements meant to ensure

12 *See NPSTC BBTF Report*.

that the public safety wireless broadband networks that develop are sufficiently robust, well-funded and interoperable, and that they are constructed within a reasonably quick time frame.[13] The present *Interoperability Public Notice* was issued to assist the Commission in gathering data and facts that would help guide the development of additional rules and policies that would be applicable to subsequent public safety regional broadband networks.

As the Commission is well aware, ensuring interoperability among the many regional networks is essential to the success of providing nationwide public safety broadband services. While providing service to roaming public safety responders is key for all networks, each local and regional public safety broadband network will have different challenges and requirements that will demand at least some level of customization. This flexibility and creativity should not be suppressed with onerous top-down regulations. Thus, Motorola recommends that the Commission set only the minimum requirements necessary to ensure interoperability among the public safety broadband networks and otherwise refrain from prescriptive regulatory mandates. This approach will allow public safety networks to develop according to the needs of their users, while also providing an interoperable foundation upon which the nationwide interoperable public safety network can be built.

Finally, to provide the best route for an advanced, interoperable, nationwide wireless broadband network that will serve public safety needs in times when emergency communications are needed most, the Commission should support efforts to obtain a reallocation of the D block directly to the public safety community. As Motorola

---

13 *See Waiver Order*.

explained in its recent analysis on the issue,[14] without the D block spectrum, public safety users will have insufficient resources to accomplish their missions during times of emergency and may even be prevented from taking advantage of the full benefits of wireless broadband technologies and applications during their day to day use. This will require greater reliance on commercial networks, even for day to day activities, which will increase operational costs for local governments.[15] Moreover, reallocation of the D block would help resolve some of the outstanding technical and operational issues identified by the Commission in the Public Notice, such as those related to roaming, network performance and interference protection.

II. Interoperability.

While granting local jurisdictions waivers to build public safety broadband networks on a regional basis, the Commission made clear that one of its fundamental goals remains the development of a nationwide interoperable broadband network for public safety services. To that end, the Commission conditioned the waiver grants on the use of the 3GPP Release 8 ("LTE") protocol air interface and additional baseline interoperability criteria.[16] The *Interoperability Public Notice* seeks comment on whether additional interoperability requirements should be imposed and implemented in its rules

15 Public safety access to commercial systems will not be free of charge but instead "[c]ommercial operators should receive reasonable compensation for public safety priority access and roaming capabilities on their networks." *NBP* Recommendation 16.1, at 316.

16 *Waiver Order*, 25 FCC Rcd at 5157, ¶ 38.

for the public safety broadband networks.[17] The public notice introduced a number of areas associated with public safety broadband interoperability, each of which are discussed below.

1. *Applications*.

Consistent with the recommendations of the NPSTC BBTF Report, the *Waiver Order* required the waiver recipients to initially support the following applications: (1) Internet access; (2) VPN access to any authorized site and to home networks; (3) a status or information "homepage;" (4) access to responders under the Incident Command System; (5) and field-based server applications.[18] The *Interoperability Public Notice* seeks comments on whether specifying these applications is sufficient for the purpose of promoting nationwide interoperability and, if so, should the requirements be codified in the rules and applicable for all future licensees.[19] The Bureau also asks whether additional applications should be required.

Motorola believes that the Commission conditioned the waiver grants appropriately through the minimum application requirements for initial deployments detailed in the *Waiver Order*. The identified applications are sufficient to support the foundational public safety usage scenarios. Motorola notes, however, that there remain many options for the design and use of these and other applications that might greatly facilitate long term interoperability. Additional decisions will be required, however, before final application determinations can made for all regions. The Emergency

---

[17] *Interoperability Public Notice*, 25 FCC Rcd at 5486.

[18] *Waiver Order* at 25 FCC Rcd at 5160, ¶ 46.

[19] *Interoperability Public Notice*, 25 FCC Rcd at 5487.

Response Interoperability Center ("ERIC"), working in consultation with its Technical Advisory Committee and the PSST, could provide a forum for these discussions and help to expedite these decisions.

Migration to standard, regional applications is envisioned to be a long-term process that must have appropriate funding, planning, and consensus within the public safety community. Motorola therefore believes that the Commission should refrain from specifying additional applications that would be available on all public safety broadband networks and, in the near term, focus instead on the underlying LTE network level interoperability that will provide the foundation for all future, broader interoperability objectives. LTE network level interoperability ensures that a public safety user device can attach, authenticate, and be provided bearer services as it roams over other regional public safety LTE deployments and participating commercial LTE networks, regardless of what application is intended to be used. Moreover, it is vitally important that public safety have continued access to the broad range of applications and services in place today that support the unique use cases of local agencies (*e.g*. Computer Aided Dispatch ("CAD"), Mobile VPN, etc.). These applications represent large investments by the agencies over several years, and their use will be essential to the effective performance of public safety's mission as agencies and users transition to next generation networks and services.

In the long term, an application interoperability strategy should be implemented to complement LTE's network level interoperability. Options for application level interoperability include: standardized User Equipment-to-Network Interface ("UNI") specifications, standardized Network-to-Network Interface ("NNI") specifications, downloadable application clients when in visited networks, or nationally hosted interoperability applications. Motorola recommends the standardized NNI approach as it accommodates the existing local and regional diversity in existing application deployments, and autonomy in future application selection, while still ensuring that public safety users can achieve the desired application interoperability.

For example, public safety CAD applications used today support Simple Mail Transfer Protocol ("SMTP") interfaces, essentially making this common format for email exchanges a method to transfer information to a CAD server for dispatch messaging to first responders. At the same time, nearly all application servers implementing Short Messaging Service (SMS) for cellular text messaging also support SMTP interfaces. So in this example SMTP could easily serve as the NNI for messaging interoperability between regions that choose to use either CAD or SMS, or both, for their local or regional messaging needs. NNI techniques are commonly used between cellular service providers to provide interoperability between their independently hosted services and can be exploited similarly for these public safety networks. Again, the ERIC, working in consultation with its Technical Advisory Committee and the PSST, would be the logical organization to oversee and expedite the development of these standards.

Recognizing that public safety devices can fall into unauthorized possession, the physical device level authentication afforded by LTE standards should be augmented with true user authentication that validates the user behind the device. For example, a means to support federated identity management when roaming must be implemented. One such option would be Security Assertion Markup Language ("SAML"), which is used widely by both enterprises and federal government agencies and can work well in conjunction with the framework that is being proposed for network level interoperability and the mandatory status/information home page application required by the Waiver Order.[20]

Imposing application performance requirements may delay deployment, thereby negatively impacting the effective use of public safety networks—especially if funding is not provided to support assured levels of performance. Operability should not be sacrificed in the name of interoperability. Motorola urges the Commission to refrain from adopting minimum application performance specifications until the approaches for roaming and application interoperability have been selected and public safety agencies have a chance to weigh in on the required application performance characteristics. The Commission should also recognize that the cost and complexity for achieving compliance with any performance specifications for application will vary greatly across different coverage areas.

2. *Roaming*.

The *Waiver Order* requires each waiver recipient's system to be capable of supporting roaming by users from all other systems authorized by waiver and from all future regional, state, Tribal and local public safety broadband systems.[21] Relying on the NPSTC's BBTF Report, the *Waiver Order* required that two categories of roaming must be supported: (1) home-routed traffic, such that a "visiting" user's traffic is routed back to the home network to enable the use of home resources, and (2) local breakout traffic,

---

20 *Waiver Order* at 25 FCC Rcd at 5160, ¶ 46.

21 *Id.* at ¶ 45.

such that a visiting user can utilize the resources of the host network.[22] The *Interoperability Public Notice* seeks comment on whether any additional roaming requirements should be added to the rules, such as handoff between public safety networks especially in case of regional emergencies.[23] The Bureau also seeks comment on the technical ramifications on public safety networks if it should adopt rules requiring or allowing roaming to and from commercial networks.[24]

Motorola supports the *Waiver Order's* requirements that the initially deployed networks support roaming through home-routed traffic and local breakout traffic. For future systems, Motorola believes that the Commission should limit the requirement for supporting roaming to home-routed traffic due to its advantages in the area of security and home-based policy control. Additional roaming requirements for future systems are not recommended.

Governance and technical parameter definitions are needed to facilitate roaming within the nationwide public safety broadband network, as well as to facilitate roaming with commercial carriers. However, a nationwide roaming clearinghouse does not need to be established initially, as this would introduce unnecessary cost and complexity for roaming scenarios that are unlikely to occur between these waiver system users and their geographically dispersed deployments. Given that the broadband network is a complex undertaking, and that LTE is a nascent technology, waiver recipients require flexibility to work out roaming arrangements and models that meet their operational needs and the

---

22 *Id.*

23 *Interoperability Public Notice*, 25 FCC Rcd at 5487.

24 *Id.*

business needs of commercial carriers. Thus, the Commission should establish only the minimum rules necessary to achieve roaming, while allowing for organic technological evolution. For example, a key roaming issue is the handling of mutual aid scenarios. Varying degrees of service levels and priorities may be desired in mutual aid scenarios, but practical limitations of technological and operational capabilities will guide the development of realistic mutual aid policies.

Waiver recipients must be allowed to develop and implement policies that provide essential capabilities within their operational and technological constraints. Evolution and refinement are inevitable as these policies get implemented and exercised, and this process should be encouraged. In this regard, Motorola endorses the recommendation of the NPSTC BBTF Report and the PSST that an advisory group made up of waiver recipients work with the PSST in establishing roaming policies and associated technical parameters.[25] This advisory group would also be responsible for recommending the long-term establishment of a nationwide roaming clearinghouse when considerations of operational and technological readiness make it appropriate.[26]

Bilateral roaming agreements between regions will be necessary and should be constructed under a common framework set by the ERIC and the PSST. However, terms and conditions of the individual agreements must be established on a regional basis, with consideration of agency-level needs and dependencies, without a federal mandate. A similar approach should be adopted as regional entities establish terms and conditions for roaming agreements with Commercial Carriers.

---

25 *See NPSTC BBTF Report* at 6.1.1.

26 *See id.* at 6.1.4.

3. *Priority Access.*

The *Interoperability Public Notice* seeks comment on the requirements for priority access on public safety broadband networks – an issue not addressed in the *Waiver Order*.[27] The Bureau states that it envisions that priority access, as a technical matter, will be commonly standardized, supported and required among public safety networks and will include, as a minimum, both the access to the common air interface and prioritization of traffic.[28] The Bureau asks whether any other elements should be included in the definition of priority access and, in general, how the capability should be implemented in public safety networks.[29]

Public safety broadband networks will need to establish priority access for both home users and public safety roamers from other regions. LTE offers the most advanced Quality of Service ("QoS") capabilities of any commercial cellular technology; however the technology must be properly configured for optimal public safety implementation and to support roaming. Motorola believes that appropriate LTE configurations should be standardized across all public safety regional systems in order to facilitate nationwide interoperability and roaming access. The appropriate national framework must contain sufficient flexibility so that each public safety region can choose a prioritization model that best suits its needs while allowing roamers to maintain consistent QoS.

When a responder roams from one regional system to another regional system (or to a commercial carrier's network), certain parameters should be standardized so that

---

27 *Interoperability Public Notice* 25 FCC Rcd at 5487.

28 *Id.*

29 *Id.*

roaming QoS can be more easily facilitated. Standardized QoS parameters are especially needed for LTE "home routed traffic" through the S8 roaming interface that the Commission has required all waiver recipients to support in the *Waiver Order*.[30] Motorola believes that the following items should be standardized on public safety broadband networks:

- ***Policy and Charging Rules Function ("PCRF").*** An optional function of the LTE architecture, the PCRF would provide QoS policy for responder devices whether at home or while roaming. Because of public safety's desire to support session-oriented, QoS-enabled traffic, home routed traffic, and roaming to both public safety and commercial carrier networks, the PCRF is essential.

- ***Access Class Barring.*** LTE includes "Access Class Barring", a method to prevent congestion of the control channel at busy Evolved Node Bs ("eNBs"). The highest class—access class 14—should be reserved for public safety first responders. This is not expected to offer significant differentiation for public safety users roaming to other public safety networks as most devices will be the same access class. However, it can provide significant benefit if and when public safety LTE devices roam onto commercial carrier networks. For this to be effective, access class 14 should be reserved for public safety usage on both commercial and public safety networks.

- ***Quality of Service Class Identifier ("QCI").*** The QCI is a scalar parameter that maps to QoS scheduling characteristics at the eNB (such as scheduling priority, packet delay budget, packet error loss rate, *etc*.). Technical standards map standard QCI values to QoS attributes.[31] When a User Equipment ("UE") roams, the QCI scalar is passed from the home to visited system. If the QoS attributes that map to the QCI scalar are different than the home system, this could result in poor (or no) application performance. It is key to require 3GPP standardized QCI scalars (and the QoS characteristics they map to) for public safety and participating commercial LTE systems.

- ***Allocation and Retention Priority ("ARP").*** LTE's ARP includes 3 attributes: 1) the priority a bearer will have for admission control at the eNB, 2) whether or not the bearer can be preempted, and 3) whether the eNB should attempt to preempt other bearers to make room for the new bearer. Motorola

---

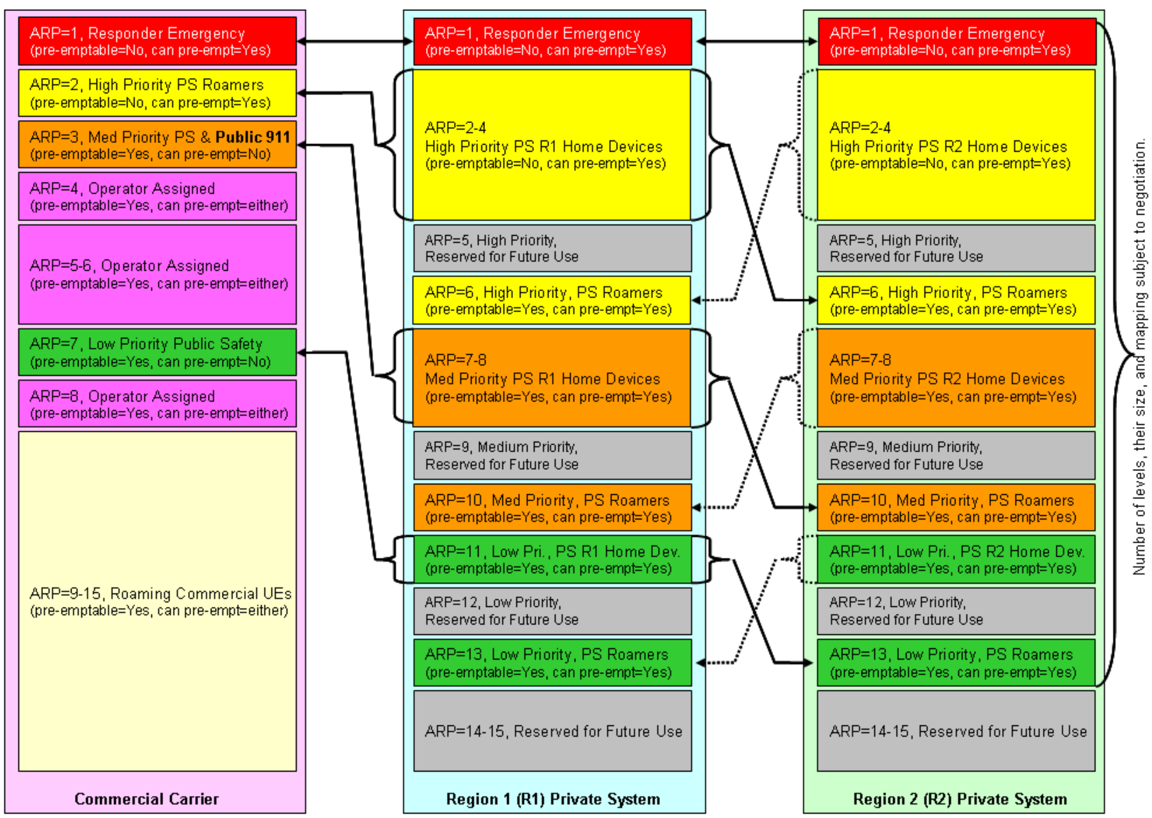
[30] *See Waiver Order*, 25 FCC Rcd at 5160, ¶ 47.

[31] 3GPP, "Policy and Charging Control Architecture" 3GPP TS 23.203 *available at* http://www.3gpp.org/ftp/Specs/html-info/23203.htm.

recommends that the Highest ARP priority be reserved for Responder Emergency, which denotes that public safety responders are in life threatening situations. Motorola also recommends that the number of ARP priority "buckets" or levels should be standardized.

The following figure provides an example of the issue of ARP and the importance of establishing a standardized number of priority levels. The example shows four priority levels (Responder Emergency, High, Medium, Low) but the actual number of levels is not critical. Once the number of levels is standardized, they must be consistently made available on both participating commercial and regional public safety systems to facilitate inter-system QoS, which is essential to a consistent roaming experience.

ARP Mapping Between Public Safety and Commercial Carrier Networks
Example for Illustrative Purposes



Within the above framework, certain standards and policies should be adopted by public safety networks to accommodate public safety roamers from other regions. During roaming scenarios, prioritization policy should be implemented such that when a public safety user roams to a visited system, the priority for that user is consistent with the visited system's prioritization policy. To accomplish that goal, Motorola recommends that the following policies should apply to the case when a public safety device (homed to a specific regional system) attempts to roam to an Evolved Packet Core ("EPC") serving another public safety region:

- ***Allow Each Region to Use the ARP Priority Levels to Fit Their Needs***. Within the confines of each priority level in the public safety regional network, public safety should be free to assign what UEs, applications, etc. map to each priority level. Today, some public safety systems prioritize based on application, and others based on responder role. Many agencies have expressed a desire for incident-based priority. This recommendation gives public safety an excellent balance between regional flexibility (whether for incident, application, device, or other priority scheme) and inter-system roaming compatibility.

- ***Public Safety Roamers Can Be Assigned to Each Priority Level.*** In order to facilitate relatively consistent prioritization between public safety regions, it is expected that roamers between regional public safety systems be allowed to utilize each of the ARP levels. For LTE home routed traffic, the home PCRF assigns the ARP priority of the bearer established in the visited system's eNB. For this reason, a consistent treatment of roamers is essential in the prioritization hierarchy.

- ***A Roaming UE's Bearers May be Preempted***. When a public safety UE roams to another public safety LTE system, the visited system should have ultimate control over its resources. For this reason, all bearers for roamers (other than the Responder Emergency level) should be susceptible to preemption.

- ***Public Safety Bearers Associated with the Responder Emergency and High Priority ARP Values Should Be Able to Preempt Other Lower Priority Bearers***. Bearers with higher priority ARP ranges must be allowed to instantly obtain resources as needed from lower priority public safety bearers.

The above standards and policies to enable priority access should not be codified in the Commission's rules. Motorola expects that public safety users, vendors and 700 MHz commercial service providers, with the encouragement and oversight of the ERIC and PSST, will find the appropriate vehicles to effectuate these types of recommendations without regulation. Even when such discussions are completed, codification of the final agreements should be eschewed in order to avoid restricting progress and innovation.

Consistent with the questions raised in the *Interoperability Public Notice*, these comments focus on priority access capabilities for public safety users on public safety broadband networks. However, if public safety is to use commercial broadband networks for public safety applications, these capabilities must also be incorporated and consistently applied to participating 700 MHz commercial LTE systems. Participating commercial operators will need to explicitly provide priority for public safety users through the use of standards based mechanisms (*i.e*. QCI, ARP). Participating commercial operators will need to implement a specific Access Class Barring policy for public safety that is timely and consistent with public safety needs. And, most importantly, public safety will require instantaneous preemptive access to commercial networks during periods of emergency. Unless these features are available to public safety users, commercial networks will not be relied upon to meet mission critical needs for first responders.

4. *System Characteristics, Interfaces and Testing*.

The *Waiver Order* imposed a number of technical specifications on the waiver recipients related to system characteristics, interfaces and testing as recommended by the

NPSTC BBTF Report.[32] The *Interoperability Public Notice* seeks comment on whether these specifications should be codified in the rules.[33] The public notice further asks if self-certification is sufficient to satisfy the need for interoperability testing on a long-term basis.[34]

In the long term, Motorola recommends the use of a self-certification relying on test suites developed specifically for public safety use of Band Class 14. These tests should be patterned after, and similar to, the tests that are applicable to other 700 MHz commercial bands and should be defined through the collaborative work of NIST, public safety representatives and the vendor community. Until a standard profile for the public safety band is established, a set of specific tests agreeable to public safety operators to enable initial deployments is recommended.

The *Waiver Order* indicated that the ERIC would consider the networks' Public Land Mobile Network ("PLMN") ID strategy.[35] Motorola urges the Commission and the ERIC to pursue this immediately in coordination with the PSST. The PLMN ID strategy will impact the number and scope of roaming instances within the nationwide broadband network; Evolved Packet Core ("EPC") equipment scaling requirements; and the statistical occurrences of application exposure to roaming transitions. The PLMN ID assignment scheme is a key element in network planning and optimization, and may be costly to modify post-deployment. Differing assumptions regarding the PLMN ID

---

33 *See Interoperability Public Notice*, 25 FCC Rcd 5487-88.

34 *Id.* at 5487.

35 *Waiver Order*, 25 FCC Rcd at 5161, ¶ 48.

scheme may lead to future interoperability delays and challenges. Therefore, a uniform approach should be adopted as soon as possible.

Motorola recommends adopting a two-pronged PLMN ID scheme whereby one unique PLMN ID is allocated for each regional entity, and one common PLMN ID is allocated for the nationwide public safety network. The unique PLMN ID per region would be used as a typical PLMN ID delineation of network administrative domains. The nationwide public safety PLMN ID may be used as a pseudonym, representing a virtual network, similar to mobile virtual network operator ("MVNO") PLMN ID's used in commercial carrier networks. The Nationwide public safety PLMN ID can also be used by entities not otherwise affiliated with regional entities, such as federal agencies. Lastly, the Nationwide PLMN ID can also be used by the public safety roaming clearinghouse for aggregating the identity of public safety entities for inter-operations with commercial carriers.

5. *Security.*

The *Interoperability Public Notice* notes that the *Waiver Order* requires that public safety equipment and devices offer technical support for all the optional LTE security features, but that the selection of the security features used will be specified by the ERIC.[36] The Bureau therefore asks what features for Key Management, Encryption, Authentication, Authorization, and Identification need to be selected in order to optimize network security.[37]

---

36 *Interoperability Public Notice*, 25 FCC Rcd at 5488.

37 *Id.*

***Application and Services Security*:**

Motorola recommends that public safety agencies continue to maintain agency-level control over key management functions, identity management functions, and authentication/authorization functions. Agencies should be able to locally manage the digital identities and credentials of their first responders. To promote interoperability between public safety agencies, Motorola recommends that agencies federate their identity, such that a responder from one agency can use their agency-provisioned identity and credentials to obtain access to other agencies services, such as the status/information homepage. The technology to enable identity federation is both mature and widely deployed across a horizontal slice of industry, including federal law enforcement, healthcare, and finance.

Technology to enable federated identity management—such as SAML—is needed for additional security.[38] SAML-based technologies bring a plethora of benefits, including enabling a single sign-on (authenticate once, authorize to many services), support for personalization (user attributes, roles), and policy control (authentication and authorization are decoupled). And, because SAML is widely used by other industries and user groups, adoption of SAML will facilitate interoperability among public safety agencies, as well as between public safety and federal law enforcement, and public safety and healthcare.

Another powerful feature of SAML is the means by which it separates authentication from authorization. SAML alone does not provide authentication; rather it asserts to a service provider that the user has been authenticated, and defines their roles and attributes. This allows authentication of the user to occur closest to the source, using already deployed agency authentication mechanisms such as Kerberos[39] or multi-factor authentication such as Smart Cards.

With respect to authentication, it is critical that not only the responder's device be authenticated, but that the user behind the device is authenticated as well. Many existing public safety applications such as CAD and voice over IP ("VoIP") telephony solutions depend upon identifying the responder in possession of the device. This is especially important in scenarios where multiple first responders will log onto an agency application through the same device, such as in the case of a fire truck with a shared Mobile Data Terminal (MDT). In such instances, simply authenticating the device is not sufficient. Motorola recommends that for public safety applications both the device and user be authenticated.

In addition to agency-controlled identity management, authentication and authorization, agencies should also maintain control over key management for their applications. Cryptographic keys managed by the network provider have a well-suited place providing defense in depth, but the ability for an agency to manage its own keys and provide end-to-end encryption of their communications must be supported by the access network. As such, encryption at either the VPN layer or application layer must not prohibit communications between the responder and their home agency applications while roaming. Motorola recommends that public safety agencies continue to maintain control over application level cryptographic keys.

---

38 *See* Section II.1, *supra* pp. 9-10.

***Network Domain Security*:**

Motorola recommends that public safety broadband networks support both the mandatory aspects of the 3GPP SAE security architecture specification as well as certain optional aspects.[40] More specifically, Motorola recommends that the following optional aspects of the security specification be applied to all public safety networks:

- Both control plane and bearer plane traffic should be encrypted over-the-air. This includes Radio Resource Control (RRC) signaling, Non-Access Stratum (NAS) signaling, and user plane traffic.

- The 3GPP security specification requires the support of both the SNOW 3G and AES encryption algorithms. AES should be the preferred choice, as it is a NIST/FIPS recommended algorithm for securing public safety communications.

Motorola further recommends adoption of the 3GPP defined mechanisms for Network Domain Security.[41] According to the standard, the interfaces between the network entities in the network are to be secured using Internet Protocol Security (IPsec) associations. The security associations will be established and maintained as stated in the standard, specifically:

- Network Domain Security / Internet Protocol (NDS/IP) inter-domain interface (Za) cryptographic protection via Security Gateways (SEGs) will be provided and is used to interface between two security domains. The Za interface security associations will be established using IKEv1 or IKEv2. X.509 digital certificate based authentication will be utilized between SEGs in different security domains.

---

[40] 3GPP, "3GPP System Architecture Evolution (SAE); Security Architecture" 3GPP TS 33.401 *available at* http://www.3gpp.org/ftp/Specs/html-info/33401.htm.

[41] *See* 3GPP, "3G security: Network Domain Security(NDS), IP Network Layer Security" 3GPP TS 33.210 *available at* http://www.3gpp.org/ftp/Specs/html-info/33210.htm.

- NDS/IP intra-domain interfaces (Zb) will be cryptographically protected unless within physically secure and/or fully trusted environments is used to interface between the various network entities within a single security domain.

Moreover, Motorola believes that the need for secure key storage in the UEs and all network entities. The level of security needed would be dictated by the security assurance required by the regional public safety network operator.

***<u>VPN Access to Home</u>*:**

Motorola recommends VPN/MVPN access to the home network for public safety users. Criminal Justice Information System ("CJIS") requirements mandate the use of FIPS 140-2 validated encryption. Therefore, Motorola recommends the use of FIPS 140 validated VPN/MVPN solutions to maintain compliance with the CJIS security policy and to access CJIS related services.

6. *Performance, Reliability, Capacity and Coverage.*

The *Waiver Order* did not address the performance, reliability, capacity or coverage of public safety wireless broadband networks and thus, the *Interoperability Public Notice* asks the general question of whether these parameters affect interoperability and what requirements for performance, reliability, capacity and coverage, if any, should the Commission adopt for the public safety broadband network and devices utilized on the network.[42] The *Interoperability Public Notice* asks whether a "network of networks" with different operational characteristics at various points hinders nationwide interoperability.[43]

---

42 *See Interoperability Public Notice* 25 FCC Rcd at 5488.

43 *Id.*

In short, the answer is no. Nationwide interoperability will be achieved by the selection of standard interoperability interfaces—most notably the LTE air interface and EPC roaming interfaces specified in the standard—with the addition of a basic set of applications for interoperability that should be defined by the PSST in coordination with the waiver recipients and the ERIC rather than included as a mandate in the rules. Performance, reliability, capacity, and coverage are all operational parameters that public safety has experience in specifying when designing and procuring systems. Interoperability does not require regulatory mandates in these areas. In fact, because the environmental and operational challenges, and thus the corresponding performance requirements, will vary substantially among regional public safety networks, any federal mandate is likely to be a poor fit to some situations and cost-prohibitive to implement for others. Motorola recommends that the Commission set only the minimum requirements necessary to ensure interoperability among the public safety broadband networks and otherwise refrain from prescriptive regulatory mandates. This approach will allow public safety networks to develop according to the needs of their users, while also providing an interoperable foundation upon which the nationwide interoperable public safety network can be built.

The *Interoperability Public Notice* further asks if the benefit of local control over these matters outweighs the benefit of service ubiquity and transparency across networks.[44] Local control of network performance definitely outweighs any perceived benefits of national service ubiquity. Regulation should not prevent local agencies from making dynamic policy decisions to enhance the priority and the performance of their

---

[44] *Id.*

users and roamers. Most appropriately, these determinations will be made under the cooperative control of the local multiagency network managers or emergency incident commander(s) who will have the authority and experience to most efficiency control the local emergency incident scene communications effectiveness. Public safety requires continued control over its broadband networks to ensure that communications can be authorized appropriately and dynamically as an incident demands.

7. *Nationwide Core.*

The *Interoperability Public Notice* notes that the *Waiver Order* requires the use of LTE and an associated Evolved Packet Core ("EPC") for each public safety regional network but does not address whether there should be a nationwide core to which all the individual networks would be connected.[45] Thus, the Bureau seeks comment on whether there should be a nationwide core created for the purpose of achieving a nationwide interoperable broadband network for public safety and, if so, how it should be operated and maintained.[46]

Motorola does not believe that a national core would be particularly useful for enhancing interoperability and may have drawbacks such as decreased nationwide reliability. LTE Standard interfaces provide both roaming and interoperability requirements without a centralized core. Further, maintaining separate public safety EPCs will allow public safety regions to independently negotiate favorable policies with different carrier networks. In short, a common EPC core provides little additional benefit

---

45 *Id.*

46 *Id.*

and limits important public safety operational requirements that can be better maintained at the local level.

8. *Network Operations, Administration and Maintenance (OA&M).*

The *Interoperability Public Notice* notes that the *Waiver Order* did not address the technological and operational features of network operations and management, administration/provisioning, and maintenance and seeks comment on what operational capability, if any, should be required in order to maintain and enhance interoperability.[47]

Public safety network deployments are expected to occur first within statewide, regional, or metropolitan areas, and to later tie-in to a nationwide level. These deployments will eventually support multiple independent jurisdictions within the overall network operational area. Each region is likely to differ in terms of needs and resources in ways that will rationally affect its decisions with respect to network operations, administration and maintenance. Standardization of network management beyond what is already afforded by common industry standards and conventions is not necessary to achieve interoperability. If a nationwide framework is initiated and if northbound interface (NBI) data from the various regional networks to the nationwide operations center is required, the minimum requirements for such an interface can be addressed by public safety and the ERIC at that time.

In addition to basic network management, additional OA&M functions can be defined to support interoperability. In the area of device management, for example, a standard protocol such as OMA-DM (Open Mobile Alliance – Device Management) should be implemented to facilitate different vendor devices being managed by the same regional network operations center. The OTA (Over the Air Activation) device management (DM) solution employed to manage the broadband networks should, at a minimum, support an OMA-DM based standardized device management interface. A vendor may still continue to support a vendor device manager and a vendor client on a handset employing proprietary technology as long as such technology supports OTA OMA-DM based management, as a baseline support.

9. *Governance.*

The *Interoperability Public Notice* seeks comment on an approach for governance of the nationwide public safety broadband network that promotes interoperability.[48] The public notice asks if the Commission should require the waiver jurisdictions to submit reports that detail the steps they are taking to align their investments to governance standards relating to interoperable emergency communications, including alignment of investments to relevant Statewide Communications Interoperability Plans (SCIP), coordination of expenditures with the grantees' Statewide Interoperability Coordinators (SWIC), and any review required by the relevant Statewide Interoperability Governing Bodies (SIGB) and network.

In supporting the initial requests for waiver submitted by the various local and state jurisdictions, Motorola urged the Commission to require the waiver recipients to obtain the approval of the PSST to deploy the regional network through a sub-license or lease agreement with the PSST.[49] Motorola stated that authorizing regional public safety

---

47 *Id.*

48 *Id.* at 5489.

49 Comments of Motorola, WT Docket No. 06-229, October 16, 2009, at 10.

broadband networks should flow directly from the nationwide license issued to the PSST as this would preserve the opportunity for ultimately achieving a nationwide network of networks to provide near ubiquitous public safety broadband access.[50] Motorola further supported one of the key recommendations of NPSTC's BBTF Report that an Advisory Group made up of representatives of the regional system operators and the PSBL be established to continue follow-on work and to provide advice to the PSST and help ensure that future network development will benefit from the best practices learned by the early adopters.[51]

Motorola believes that these basic requirements provide the best governance framework for the public safety broadband spectrum. Under the oversight of the ERIC, regional public safety operators should be encouraged to share information and best practices with the PSST to assist with the development of future networks. Additional reporting requirements beyond those implemented by the *Waiver Order,* should not be imposed but the ability of the ERIC and the PSST to solicit information from regional operators should be clarified.

III. Out-of-Band Emissions.

The *Waiver Order* imposed out-of-band emissions ("OOBE") requirements on public safety broadband base stations and user equipment of 43+10log(P) outside of the licensed frequency block.[52] The *Interoperability Public Notice* seeks comment on the sufficiency of this requirement and further asks what steps can be taken to make the

---

[50] *Id.* at 7.

[51] *Id.* at 6.

[52] *Waiver Order*, 25 FCC Rcd at 5159, ¶ 44.

equipment deployed via waiver comply with more stringent standards that may be adopted in the future.[53]

Motorola recommends that base stations be required to meet the current provisions of Section 90.543(e) that specify an OOBE attenuation requirement of 76+10log(P) per 6.25 kHz in order to minimize interference to public safety narrowband operations in the 769 – 775 MHz and 799 – 805 MHz bands. The 3GPP TS 36.104 standard has incorporated these public safety protection requirements as regional options[54] and 700 MHz base stations that are compliant with this requirement have received FCC equipment certification. For base station OOBE that fall into commercial portions of the 700 MHz band, the 43 + 10log(P) specification is appropriate.

With regard to UE, Section 90.543(e) requires OOBE emissions in the public safety narrowband blocks to be attenuated in accordance with the specification 65 + 10 log(P). Compliance with this requirement is an issue in the short term. A preliminary analysis of Band Class 14 with some of the performance specifications added to 3GPP TS 36.101[55] had been performed in 3GPP RAN4, but without the final D block rules, the work was not completed. Recently, 3GPP RAN4 has begun work on Band Class 14 devices with respect to meeting the requirements of Section 90.543(e), Section 27.53(c)

---

53 *Interoperability Public Notice*, 25 FCC Rcd at 5489.

54 3GPP, "Evolved Universal Terrestrial Radio Access (E-UTRA); Base Station (BS) radio transmission and reception" 3GPP TS 36.104 *available at* http://www.3gpp.org/ftp/Specs/html-info/36104.htm.

55 3GPP, "Evolved Universal Terrestrial Radio Access (E-UTRA); Mobile Station (MS) radio transmission and reception" 3GPP TS 36.101 *available at* http://www.3gpp.org/ftp/Specs/html-info/36101.htm.

and Section 27.53(d) of the Commission's Rules. Motorola is supporting this work[56] and expects that 3GPP will soon address these Band Class 14 specifications. Until then, Motorola concurs with the Commission that waiver recipients be allowed to operate UE devices that meet 43 + 10log(P) into the public safety narrowband 700 MHz allocation. Because this offers less protection that the Commission's rules, waiver customers should coordinate their LTE deployments with any 700 MHz narrowband operations in order to minimize the potential for interference as specified in the Commission waiver grant. The existing provisions of Section 90.543(e) should be maintained in order to provide necessary protection for critical public safety systems. Since this rule has long been published and applied to the existing 700 MHz band deployments, vendors should be well versed in the requirement and in existing 3GPP maximum power reduction techniques that may be added for Band Class 14 operations.

The *Interoperability Public Notice* asks whether it would be possible to further attenuate signals outside the public safety band without a guard band between D block and the Public Safety Broadband ("PSBB") block if more stringent OOBE limits are applied to the PSBB spectrum than those applied in the *Waiver Order*.[57] Motorola believes that this is not a feasible solution to the spectrum coexistence problem that will exist between independent D block and PSBB networks operating on adjacent frequencies. A guard band between these two blocks will be necessary to account for the different network topology used by public safety (*i.e.*, relatively high tower and larger cell sites) as compared to D block commercial broadband (high to medium tower and

---

[56] *See* Motorola, R4-102686, 3GPP TSG-RAN4 Ad Hoc #2010-03,"*FCC emission requirements for B13 and B14*", Bratislava, Slovakia, June 2010

[57] *Interoperability Public Notice*, 25 FCC Rcd at 5489.

high density cell sites). Additional filtering in most cases would be ineffective and/or infeasible for adjacent 5 MHz LTE channels. In particular, further reduction of the base station OOBE will not be effective because the downlink interference path (*i.e.*, interference from base stations to adjacent channel LTE user equipment) is dominated by the UE Adjacent Channel Selectivity (ACS) specification of 33 dB (3GPP TS 36.101) and not the LTE base station Adjacent Channel Leakage Ratio (ACLR) of 45 dB (3GPP TS 36.104). Changing the LTE user equipment ACS specification is not practical because it would force fundamental changes to the chip set and the UE receiver design.

Conversely, interference in the uplink path (*i.e.*, interference from user equipment to adjacent channel LTE base stations) is dominated by UE OOBE rather than base station ACS and there is little that can be done about it other than restricting UE transmitter power and transmission bandwidth. This solution comes at the expense of uplink coverage and capacity. However, the uplink path is believed to be less problematic from an interference standpoint than the down link due to the much lower power of the UE compared to the base station. In short, the need for a guard band between independent 5 MHz LTE networks operating on the D block and the PSBB is predicated primarily on the interference in the downlink path from relatively high powered base stations interfering with nearby UE and this interference is largely unaffected by further reduction in base station OOBE.

Interference to public safety UE on the downlink is a serious concern because it leads to coverage holes around the D block's base sites. Fundamentally, there are three approaches to minimize this interference problem to PSBB UE: 1) reduce the bandwidth of emissions in the D block and/or PSBB to 3 MHz to create a guard band, 2) deploy similar network topologies in both D block and PSBB spectrum (which may or may not co-locate D block and public safety base sites) and 3) combine the D block and PSBB spectrum into a single 10+10 MHz block for public safety utilization. Reducing bandwidth to create a guard band is inefficient and, in the case of public safety spectrum, totally unacceptable given their already inadequate allocations. The deployment alternative requires that a PSBB site reside at every D block site (and vice versa) or at similar site spacing forcing public safety operators to build capacity equal to the commercial operator even if it is not necessary or economically viable. Even if the funding were available, the logistics of keeping commercial D block operators and public safety site development in lock-step are not workable as commercial carriers are constantly optimizing their network for their performance tuning driven by economic business models. There is also the scenario where the D block carrier deploys temporary site(s) for special events. Such sites will be an interference source to public safety users located at the same event as the public safety users will likely be located further away from the public safety base site.

One advantage of combining the D block and PSBB block can be seen in the following scenario. If the blocks remain independent, a C block commercial operator deploying equipment compliant to 3GPP band class 13 would utilize 746-756 MHz band, the D block commercial operator would utilize 758-763 MHz, and the public safety network would utilize 763-768 MHz. A combined D block/PSBB block would allow a public safety system to utilize 758-768 MHz. The public safety system would then have a 2 MHz guard band between it and the 3GPP band class 13, which would result in improved receiver selectivity between the public safety system and the adjacent commercial system, the impact of which can be evaluated using coverage modeling.

The following picture uses coverage modeling to show the impact of a non-collocated D Dlock network on PSBB coverage (case 1).[58] This is contrasted against the impact that a non-collocated network operating in the Upper 700 MHz C block would have on a public safety network from combining the D block and PSBB block (case 2). The difference between the two cases is that there is no guard band in case 1 and there is 2 MHz of guard band in case 2.

	D-Block 5MHz BTS to PSST 5MHz UE (0 MHz Guard Band)	C-Block 10MHz BTS to (D + PSST) 10MHz UE (2 MHz Guard Band)
Throughput Loss	Average: 7.9% Near Site: 55%	Average: 3.1% Near Site: 28%
Outage Increase	Average: 2.4% Near Site: 22%	Average: 0.8% Near Site: 8%

58 This scenario was based the 3GPP TR 36.942 parameters of 20W base station power and base to UE antenna minimum coupling loss (MCL) of 70 dB. Many LTE base stations will have more power and will be have lower antenna heights thus reducing the MCL below 70 dB that we used. These are typical parameters and the interference can be better or worse based on actual deployments.

Coverage outage in the public safety block due to the D block sites for case 1, or the C block sites in case 2, is caused by the signal strength of the cellular base station signal exceeding the signal strength of the desired public safety base station signal by 43 dB.[59] This is attributed to differences in public safety and commercial broadband network deployment topology. The red dots in the picture show outage in the PSBB block due to interference from the D block and the green dots show outage in the combined D/PSBB block due to the C block.

Public safety is more concerned about small coverage holes than typical commercial operations, which balance other factors in their deployments. The analysis shows the public safety system's average outage can be reduced from 2.4% to 0.8% when combining D block and the PSBB block. For locations nearest the D block transmitter sites, the effect of joining the D block and the PSBB block together reduces the outage area from 22% to 8%.[60] Reduction of throughput due to adjacent channel interference is also shown in the table in the figure. The table shows that average throughput is not significantly affected by adjacent channel interference. The impact of low ACS to average throughput is less of a concern to commercial operators than the resulting coverage holes are to public safety operations.

---

59 This was calculated as 33 dB for ACS and -10 dB SINR for the interference criterion. This is the most optimistic approach as LTE operation at -10 dB SINR produces the lowest usable data rates of approximately 0.06 bits/Hz (or only 10 kb/s per 180 kHz LTE subchannel). Increasing this threshold SINR to provide better performance levels for Public Safety will force even more coverage holes around C block or D block sites.

60 The 22% outage is calculated over the area within 80 meters of D block sites that are at least 500 meters away from the PSBB sites. The holes in coverage can be seen by

IV. Equipment Certification.

In the Waiver Order, the Commission waived the equipment certification requirements of Section 90.203 of its rules and instead required manufacturers to comply with the various technical requirements of 3GPP Release 8 LTE specifications pending finalization of the rules.[61] The *Interoperability Public Notice* seeks comment on the impact of any future rules adopted by the Commission on equipment deployed prior to the adoption of final rules.[62] The Bureau further asks how the continuing evolution of the 3GPP standard from Release 8 LTE to future 3GPP releases should be handled such that there is minimal impact on deployed equipment while continuing to provide necessary functionality.[63]

The Commission must be careful to avoid paralyzing the development of new technologies by over-reliance on the regulatory process to establish rules and standards. While technical standards ensure interoperability and provide manufacturing economies of scale that help drive down the cost of devices, codification of these standards into the Commission's rules will potentially subject advancements and enhancements to lengthy rule making processes before being approved. If public safety operators are to benefit from technology platforms that are shared with commercial networks, they should have similar opportunities to deploy next generation advancements without lengthy Commission approval. Motorola urges the Commission to consider how the ERIC can be

---

the grouping of the red dots near the D block sites. The green dots show some amount of grouping, too, but to a much less degree.

61 *Waiver Order*, 25 FCC Rcd at 5157 n.88.

62 *Interoperability Public Notice*, 25 FCC Rcd at 5489.

63 *Id.* at 5490.

utilized to review new technologies and issue technology recommendations outside of the rulemaking process to guide public safety purchase decisions. Future designs of LTE will almost certainly retain backward compatibility with all of the baseline interoperability requirements.

Motorola believes that to promote the deployment of public safety broadband networks, it is essential that it define only those standards necessary to ensure roaming and interoperability. The Commission should attempt to minimize the impact of any future rules on the waiver recipients and other early adopter and avoid regulations that require replacement of initial products and designs.

V. Conclusion.

The development of public safety broadband networks is an ambitious task that surpasses all previous efforts to enhance the communications capabilities of America's first responders. The Commission, vendors and users will all benefit greatly from the experiences of the waiver recipients as they deploy the first public safety grade wireless broadband networks. While the Commission, through the ERIC, should keenly monitor the deployment of these networks to ensure that interoperability is preserved, it should refrain from establishing requirements for applications or performance standards, especially at this early stage of development.

Re: PS Docket 06-229
WT Docket 06-150

Dear Ms. Dortch:

Pursuant to Section 1.1206(b)(2) of the Commission's Rules, Motorola submits this written ex parte filing in the above captioned proceeding.

On June 15, the Commission released a staff white paper titled *The Public Safety Nationwide Interoperable Broadband Network: A New Model for Capacity, Performance and Cost* ("staff white paper"). The staff white paper purports to show that:

1) The 10 MHz of dedicated broadband spectrum allocated to Public Safety in the 700 MHz band for broadband communications provides more than the required capacity for day to day communications and scenarios the staff selected to analyze; and

2) For the worst emergencies even access to another 10 MHz of spectrum would be insufficient.

The staff white paper then concludes that in these situations, priority access and roaming on the 700 MHz commercial networks is the solution.

Motorola respectfully disagrees with the staff's analysis and conclusions in this white paper. As addressed in the attachment, many of the assumptions used in this paper apply to commercial systems and consumer requirements but are inapplicable to Public Safety broadband operational requirements. In addition to covering issues specifically pertinent to the staff white paper, additional implications for Public Safety of the staff's recommended plan are addressed herein.

Pursuant to the Commission's Rules, one copy of this notice is being filed electronically with the Commission. If you require any additional information please contact the undersigned at (202) 371-6900.

Respectfully submitted,

/s/ *Rob Kubik*
Robert D. Kubik, Ph.D.
Director, Telecom Relations Global

MOTOROLA

The staff's capacity analysis suggests that 10 MHz (5+5 MHz) of dedicated spectrum provides the required capacity and the required performance for serious emergency scenarios. Is this analysis correct?

No. Public Safety agencies do not get to predict or choose where an incident will occur. They must respond wherever the need occurs within their jurisdiction. Therefore, as Public Safety systems deploy new broadband technology, the systems must be designed to meet anticipated requirements throughout the jurisdiction or region for which the system is designed, whether the incident occurs at the center of a cell or on the cell edge. The staff's analysis is based on average sector capacity which may be applicable to consumer based deployments, but does not accurately model the network performance required for mission critical broadband Public Safety operations. These Public Safety broadband operations must be highly reliable and available even on the cell edge, to the extent possible. The cell edge capacity of any technology, especially single frequency reuse, self-interference based technologies, exhibits much less user and sector capacity on the edge of a cell. For example, based on 3GPP requirements, the average per user throughput in a sector is approximately 3 times that of the edge throughput per user.

Performance based on 3GPP TR 36.913 V9.0.0 (EUTRA Advanced Requirements)						
Communications Direction	**Antenna Config. (TxR)**	**Average Spectrum Efficiency (Sector bits/Hz.)**	**Cell Edge Throughput (per UE bits/Hz.)**	**Average to Edge Ratio (per UE)**	**5+5 MHz Average Sector Throughput (kb/s)**	**5+5 MHz Cell Edge UE Throughput (kb/s)**
Uplink	1x2	1.2	0.04	3.0	6000	200
Uplink	2x4	2.0	0.07	2.9	10000	350
Downlink	2x2	2.4	0.07	3.4	12000	350
Downlink	4x2	2.6	0.09	2.9	13000	450
Downlink	4x4	3.7	0.12	3.1	18500	600

Therefore, the staff white paper overstates the capacity that would be available to agencies when an incident occurs at a cell edge. The capacity available at the point of an incident is what is relevant, not the average capacity throughout a cell. The staff white paper also seems to believe that any capacity problem can be solved just by adding more cell sites. This appears to ignore the many practical tradeoffs of adding cell sites such as increased need for backhaul links and spectrum, zoning, and cost, especially for Public Safety grade facilities.

Additionally, the staff's analysis does not accurately reflect the capacity demand. A successful solution must fully comprehend and address the needs of the Public Safety community as defined by that community. Motorola's customer research indicates the Public Safety community will require 400-1200 kb/s for tactical decision making. We have used state of the art video codec's to ensure efficient operation and have done trade-off analyses with customers who project that they will need these higher rates and the resulting higher quality video to allow for tactical operations. For example, the video could need to show whether a suspect is holding a bomb…or a baby.

The staff's white paper significantly reduces the anticipated required video data rate down to 256 - 512 kb/s while relying on the Project Safecom document.[1] While the report suggest that 256 – 512 kb/s may be sufficient for the video system under certain prescribed constraints, the report has most all items as either "Under Study" or "Not Specified" for the video acquisition and video display systems. One should not draw a formal conclusion from this previous unfinished work. We suggest that the Project SAFECOM video performance subject be revisited and evaluated by the Public Safety community and industry before any hard conclusions can come to consensus.

The staff use of average sector capacity, coupled with low-rate, low quality video, skews the analysis. Assumptions more applicable to Public Safety operational requirements should be used when predicting capacity and spectrum requirements for a mission critical broadband environment.

Why does Public Safety need the D block spectrum?

It is contradictory to predict that Public Safety will be limited in its broadband requirements while at the same time accepting that consumer requirements for broadband will soar. To the contrary, Public Safety has identified a host of applications for broadband. Public Safety agencies will be able to utilize the data applications in place today with faster, more responsive performance, increasing their utility and benefit. Also, sufficient broadband capacity can offer access to a whole array of advanced, multimedia applications that take advantage of key enablers including:

- Bi-directional, vehicular and portable video
- Location aware real-time services
- Mobile office, in-field productivity
- Multimedia command & control
- Dynamic mapping, weather & traffic flows
- Content-rich lookups to complex databases
- Biometric data

The Public Safety broadband network can provide greater efficiencies in day-to-day Public Safety operations, management of emergency incidents and major events, as well as providing the critical support needed for catastrophic incidents. Failure to reallocate the D block to Public Safety will limit its ability to get the full use of these applications.

Given the likely increased Public Safety data consumption, Public Safety agencies that are constrained on their own network will face increasing data roaming costs to support capacity requirements on a commercial network. We note that one major carrier recently adjusted its rate plan to effectively eliminate its unlimited tier in an effort to moderate demand from users with greater airtime requirements.

[1] Public Safety Statement of Requirements for Communications and Interoperability, (Project Safecom Document) Volume II Version 1.2 2008.

MOTOROLA

How will the staff's plan impact multi-agency interoperability?

Broadband has been promoted as a solution for Public Safety interoperability by Congress, the Commission, the Public Safety community and industry. Public Safety operations require multi-agency coordination. Even a fairly routine incident may call in over 100 responders and over 50 vehicles – all requiring coordinated, interoperable communications. More expansive incidents like the 2007 Minneapolis I-35 bridge collapse had over 128 agencies and over 1200 first responders involved in the rescue operations.[2]

Public Safety communications capacity requirements have exceeded every spectrum allocation made throughout the years. Even with improvements in technology and efficiency and sharing of systems among multiple jurisdictions, growing requirements have exceeded the spectrum capacity available. Unfortunately, continuing the same history by providing Public Safety the minimum allocation possible at the outset of broadband deployment negatively impacts the ability to ensure effective interoperability across all levels of government. Refusing to reallocate the D block to Public Safety will result in the need for future Public Safety broadband allocations that ultimately have to be sourced from another spectrum band, further hampering interoperability and significantly increasing the cost for deployment, as well as ongoing operations and maintenance.

Will reallocating the D block to Public Safety increase the cost of the network and associated devices and evaporate the benefits of aligning to the broader commercial LTE market?

No. Public Safety will benefit from a healthy, commercial market-driven ecosystem at 700 MHz. Verizon Wireless, AT&T and other carriers have committed to using LTE for their 700 MHz deployments.[3] In fact, LTE will be the dominant commercial platform across the overwhelming majority of the commercial 700 MHz allocation. Critical mass has been achieved and the commercial eco-system at 700 MHz will not be affected by a decision to reallocate the D block. From a base transceiver (eNodeB) standpoint, we already see vendors in the process of offering Band Class 14 equipment to the Public Safety Communications Research test bed, so those investments have already been made. Also, regardless of whether the D block is reallocated, roaming across other 700 MHz commercial systems as the Commission's National Broadband Plan recommends would require devices to cover one or more commercial 700 MHz LTE band classes.

Can roaming onto carrier networks eliminate the need to dedicate the D block to Public Safety?

No. The staff's white paper positions priority access and roaming onto commercial networks as the solution, in lieu of providing Public Safety sufficient dedicated spectrum. However, large scale incidents requiring Public Safety to utilize commercial spectrum under the staff's plan, are the very same times that such incidents dramatically increase commercial networks demand and make them congested and least available to other users.

Public Safety has first hand knowledge of the need to control its communications networks. Many disaster situations have shown that commercial systems get clogged with drastic increase in demand, just as Public Safety systems do. Even priority access (without pre-emption) on a clogged commercial system does not guarantee Public Safety access to the capacity it will need.[4]

Furthermore, commercial systems are necessarily built to meet the needs of consumers, not the higher levels of reliability, availability, in-building coverage, and user feature flexibility inherent in dedicated Public Safety networks. For the worst emergencies, most commercial networks will not be available since their hardening and reliability is often less than that of the typical dedicated Public Safety system. Even the staff's previous proposals that envisioned additional hardening for commercial networks did not apply to all commercial systems. Therefore, depending on where the emergency occurs, Public Safety may or may not have service from roaming.

A Public Safety responder handing over to the commercial network looking for capacity may discover that the sites are down or overloaded and experience dropped service connections. There is no device visibility to the status of other networks and no guarantee that capacity will be available when switching between networks.[5]

In times when commercial networks are available, roaming onto a commercial carrier with priority access will offer a significant back-up capability. However, the costs of roaming, priority access, and data usage have not been factored into the staff's cost model. With overly-limited Public Safety spectrum, these costs will be considerable in daily emergency situations as well as major incidents.

Additionally, commercial LTE prioritization policy as defined in the 3GPP standard cannot distinguish between Public Safety incidents.[6] There is no ability to distinguish between a firefighter responding to a cat in a tree one day or a 4 alarm fire the next day.

MOTOROLA

What is “pre-emption” and why is this important to Public Safety?

“Pre-emption” is the ability to immediately drop active communications of low priority users off of the network during emergency incidents to direct necessary capacity to critical public safety user communications. This is an important feature that is built into the foundation of Public Safety mission critical voice communication systems.

Priority access alone without pre-emption, as the FCC staff has suggested, would not guarantee immediate access to public safety users. It only puts that a public safety user’s request at the head of the queue waiting for available bandwidth to free up. The higher priority public safety user would not be allocated bandwidth if the non-priority users were active in guaranteed bit rate sessions, as are used for real-time video and voice communications. For example, citizens at the scene of an emergency who are streaming video from their smartphones to their friends, or in phone calls with their friends, could tie up the commercial bandwidth and prevent public safety access until a citizen ended his/her session and made the bandwidth available. Priority access alone is therefore unacceptable for time sensitive public safety communications, and pre-emptive access would be required.

Can Public Safety rely on commercial carriers to provide pre-emption capabilities during critical incidents?

While providing pre-emption on a commercial network would be necessary for Public Safety operations, doing so would not be viewed as a positive experience by consumers booted off the network during an emergency. Also, requiring pre-emption on all commercial networks would essentially change the terms of operation under which operators have acquired spectrum in the previous 700 MHz band auction. A further policy challenge is deciding the priority level of next generation 911 calls by citizens with respect to the priority of communications from Public Safety users. Next generation 911 calls may involve high bandwidth video sessions.

What is the impact to the public of removing the D block from the auction?

First, dedicating spectrum to further empower Public Safety with broadband tools benefits the entire public community being served by police officers, firefighters and emergency medical personnel. Without adequate safety and homeland security, the entire U.S. economy and way of life suffers. Second, removing the 10 MHz of the D block from the auction would be only a 2% impact on the 500 MHz the Commission has targeted for overall commercial broadband operations.

In contrast reallocating the D block to Public Safety can effectively double the capacity guaranteed to be available to protect public life and property and help ensure homeland security by reducing Public Safety’s reliance on commercial networks that are often inadequately designed to meet Public Safety’s operational needs.

Furthermore, removing the D block from auction does not prevent Congress from appropriating funding for Public Safety broadband deployment. The Administration and the Commission are promoting making 500 MHz of spectrum available for commercial broadband. Should Congress choose to support Public Safety through auction revenues, doing so should be accomplishable even if the D block is reallocated and not auctioned. In unveiling the Administration's proposal, Larry Summers, Director of the National Economic Council advised that Public Safety would have first claim to revenue generated by the spectrum auctions.[7]

How do we know what quality of video is really required for Public Safety operations?

The Department of Homeland Security has established the working group Video Quality in Public Safety (VQiPS) to determine standards around video presentation in various Public Safety use cases.[8] While the industry awaits the analysis and outcomes from the working group, Public Safety agencies along with leading technology vendors have identified requirements for higher video quality and data rates. For example, New York's DoITT (Department of Information Technology and Telecommunications) has specified requirements for 1-2 Mbps cameras supporting mobile operations:

> The system shall be able to support full motion video (30 frames per second) or data transmission speeds in excess of 2 Mbps at anytime to any one user regardless of any other network activity.[9]

Will increasing advancements in video technology allow us to transmit higher quality video using less spectrum in the near future?

On the one hand, video encoding and compression advancements anticipated in the next decade will shrink the transmit size of a given video stream by increasing the optimization of rate control, motion estimation, and adaptive noise reductions. There will also be some improvements in the LTE technology over time. However, at the same time, the number of users and traffic on both the Public Safety and the commercial networks will continue to grow. In addition, as history on both Public Safety and commercial networks has shown, valuable new applications will come to market that need more and more bandwidth to serve each user. Public Safety and the Commission all anticipate that Public Safety will need more bandwidth to accommodate this trend. This analysis is wholly consistent with the Commission's and the administration's desire to find an additional 500 MHz for commercial broadband networks.

[9] City of New York, Department of Information Technology and Telecommunication, Request for Proposal, Citywide Mobile Wireless Network, March 24, 2004.

Commercial demand for more spectrum is being driven by the amount of bandwidth required for each user, an increasing number of broadband users and a broader set of users, including machine to machine, at the same time efficiencies in bandwidth delivery improve. The same is true for Public Safety services.

Today, Motorola's analysis shows that 10 MHz alone will not support expected Public Safety video applications for real-time incident scene decision-making.[10] Thorough analysis and modeling by Public Safety agencies and leading vendors have considered the state-of-the-art, best-in-class techniques for video encoding and compression to determine the baseline capacity needs from the broadband network. Public Safety's bandwidth constraints will only worsen over time.

Can Public Safety use delayed video or image grabs to alleviate the capacity concerns?

Delayed video is video that is transmitted at a lower rate (bits per second) than the rate at which it was captured (seemingly because of a limitation in the network's transmission capacity or in an attempt to take advantage of non-real-time compression techniques). Transmitting video in this way causes two problems. First, the video seen on the receiving end will not be real-time, so Public Safety decision making suffers.

Second, since the outgoing bits move more slowly than the incoming bits, the camera's buffer will fill and it will have to stop recording until it catches up. Video transmission that is not real-time and has large holes endangers the response by influencing decisions based on misinformation regarding the current state of the situation. Image grabs (i.e. transmitted pictures) present the same problem, but are even more limiting. For example, assessing whether an incident is escalating (decision: send more resources) or calming down (decision: do not send any more resources or switch to clean-up resources) would be severely impaired. Decisions made and actions taken can determine the extent of lost lives and damage. The most effective Public Safety response will require real-time, situational awareness of the incident as it unfolds.

Will auctioning the D block to a commercial operator result in interference and coverage holes for Public Safety?

Yes. Interference based coverage holes will result in unexpected and unpredictable dropped calls for emergency responders.

- Coverage holes appear due to adjacent channel interference between D block Base Sites and Public Safety Base Sites.

[10] Motorola Ex Parte presentation, WT Docket 06-150 and PS Docket 06-229, April 12, 2010.

- The coverage holes may appear anywhere across the broadband coverage area as RF shadowing and multipath phenomenon create unpredictable coverage gaps where a user connection would become suddenly terminated.
- The probability of a coverage hole appearing increases when the Public Safety user travels toward the coverage edge of a Public Safety Base Site and arrives in proximity to a D block site.
- As the D block commercial operator builds out their network to increase coverage in "hot spots" or indoor locations using microcells or picocells; the probability of a coverage gap will increase.
- Coexistence analysis methods used for purposes of commercial carrier spectrum allocations, and which the staff has relied upon, are focused on overall sector throughput reduction measurements and not on specific areas of coverage outage and capacity degradations, which is necessary for determining the impact to mission critical public safety communications. [11]
- Users traveling within 80 meters of a D block site increase their probability of a sudden communications outage by over 20% and a capacity degradation of over 50%.[12]

Public Safety cannot predict or plan where an incident will occur. If an incident occurs at the location of a coverage hole, the impact is significant, even though the "average" impact throughout a cell or sector may be viewed as low.

In short, disassociating the D block from the Public Safety broadband spectrum will result in interference scenarios similar to those experienced by Public Safety in the 800 MHz band. The plan to resolve the 800 MHz interference is currently in its 6th year with no end in sight and is likely to cost the industry more than $4 billion to complete.

The only practical solutions to mitigating this potential interference are spectrum guard bands or co-located base stations facilities between Public Safety and the D block networks. Assuming the guard bands would come from the commercial spectrum allocations, this would disadvantage D block licensees from a competitive business perspective. Any required co-location of commercial and Public Safety base sites effectively prohibits public safety from competitive partnerships with other 700 MHz carriers, and introduces substantial issues with coordinating the timing of deployments between public safety needs in a given region and the commercial D block operator's budgets and operating plans.

Can filters be used to suppress the interference between the D block and the Public Safety PSST spectrum?

No. The major interference scenario is D block base site transmitter power coming into public safety handsets in their adjacent spectrum. Practical duplexer filters that can fit into a handset form factor are not narrow enough to significantly attenuate the adjacent D block signal. A

[11] Motorola Ex Parte presentation, WT Docket 06-150 and PS Docket 06-229, April 12, 2010.

[12] Motorola Ex Parte presentation, WT Docket 06-150 and PS Docket 06-229, April 12, 2010.

forced guard band and/or reduced power allowance on the D block may help reduce the extent of this interference. Further, any guard band between the D block and Public Safety would essentially reduce the D block to only 3+3 MHz of spectrum if compliance with the LTE standard is maintained because the next channel size below a 5+5 MHz channel in the standard is 3+3 MHz .[13]

How does the staff's plan impact competition and fair play among commercial carriers?

The staff's plan eliminates competition and hampers fair play, to the disadvantage of both Public Safety and commercial carriers. There are only two foreseeable options (as challenged as they are in other ways) to manage the interference between the Public Safety block and the D block. In a any given area, 1) the D block winner implements a guard band and is reduced to a 3 MHz channel, i.e., the next size down from 5 MHz in the LTE standard; or 2) the Public Safety and D block site deployments must be collocated and coordinated such that Public Safety will have no option but to work exclusively with the D block winner in that area.

Under option 1, the D block winner is obviously disadvantaged from a business perspective. In option 2, Public Safety agencies will be disadvantaged because their freedom of choice is removed and the D block winner becomes a sole-source partner for life. Public Safety will be forced to the terms and conditions of an adjacent neighbor motivated by consumer services. Maintenance and service upgrades of shared equipment will be dictated by the priorities of the D block winner, a profit-motivated consumer-focused business that knows it has a captive audience.

Further, the commercial auction regions chosen by the Commission may not align with practical regional areas for Public Safety broadband systems, requiring Public Safety to coordinate with multiple D block winners.

Commercial carriers outside the D block are disadvantaged by being kept from effectively competing on a level playing field to win new Public Safety LTE business. Additionally, all existing Public Safety subscriptions are likely to churn to the D block winner.

How do differences in LTE systems and Public Safety voice systems impact the need for spectrum?

The staff has made a point in its white paper to note that broadband systems differ from current land mobile radio (LMR) technology. LTE broadband systems will greatly improve data communications for Public Safety by offering data rates unattainable on current public safety voice networks. In addition, as noted above, the choice of LTE for broadband public safety

[13] TS 36.101 V9.4.0 E-UTRA Users Equipment (UE) radio transmission and reception (Release 9)

systems can help leverage equipment economies of scale as two major commercial operators have already chosen to deploy LTE in their 700 MHz band segments.

However, the real issue at hand is not the differences in current LMR voice system and LTE systems, but the fact that Public Safety's broadband capacity needs will expand similar to those already accepted by the Commission for commercial networks and general consumers. Whether commercial operators/consumers or Public Safety agencies, systems must be designed to meet a combination of needs, not just capacity. Therefore, the spectrum available is the key parameter that affects the capacity available, as the Commission staff has readily accepted for commercial/consumer requirements but seems to reject for Public Safety.

The staff white paper claims that Public Safety already has per-user spectrum allocations that are 25 times that of a commercial provider. Is this correct?

The staff states that in a comparison of users per MHz of spectrum that the ratio of commercial users per MHz is 25 times that of Public Safety users per MHz. Unfortunately, the staff uses an "apples-to-oranges" comparison that is irrelevant at best. The real issue is not just the number of users, but also the amount of usage and type of usage compared to operational requirements.

Even if one assumes the comparison were relevant, the ratio is only about one tenth of that the staff claims.[14] Out of the 97 MHz of Public Safety spectrum the staff considered in its calculation, 50 MHz comes from the 4.9 GHz band which the white paper clearly recognizes is well-suited only for "fixed" deployments. For mobile broadband capability, Public Safety today only has the 10 MHz allocation at 700 MHz. If one takes out the 50 MHz of spectrum the staff states is better for fixed deployments and adds in the 500 MHz of additional spectrum the staff will allocate for commercial use, the number is closer to 2.7 times.[15] Again, even this number is irrelevant. With the growth in broadband applications, it is not unreasonable to believe that a Public Safety user's capacity demand at an emergency will be greater than that of the average consumer user.

The staff has suggested that it will give Public Safety additional spectrum sometime later, why isn't that good enough?

The fact that the D block is directly adjacent to the Public Safety band allows Public Safety to build one network, double its capacity, solve the interference issue, eliminate dropped calls and allow Public Safety to keep up with advancing requirements. Having the two bands combined to serve one network significantly reduces the cost and complexity of the network equipment and devices compared to having the spectrum split across two non-adjacent bands. Additionally, by combining the two bands, Public Safety could utilize the entire 10 MHz where having the D

[14] Staff white paper, page 3.

[15] Staff white paper, page 10.

block separated will necessitate wasting spectrum to carve out a guard band between D block and Public Safety.

This approach repeats the history of providing Public Safety with additional spectrum allocations in differing bands that are not easy to integrate and thus frustrate Public Safety interoperability. This is precisely what the 700 MHz allocations were intended to address.

Appendix E – Bill Language

II

Calendar No. _____

112TH CONGRESS
1ST SESSION

S. 911

[Report No. 112–_____]

To establish the sense of Congress that Congress should enact, and the President should sign, bipartisan legislation to strengthen public safety and to enhance wireless communications.

IN THE SENATE OF THE UNITED STATES

MAY 9, 2011

Mr. ROCKEFELLER (for himself and Mrs. HUTCHISON) introduced the following bill; which was read twice and referred to the Committee on Commerce, Science, and Transportation

_____________ (legislative day, _____________), _____

Reported by Mr. ROCKEFELLER, with an amendment

[Strike out all after the enacting clause and insert the part printed in italic]

A BILL

To establish the sense of Congress that Congress should enact, and the President should sign, bipartisan legislation to strengthen public safety and to enhance wireless communications.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,

~~**SECTION 1. SHORT TITLE.**~~

~~This Act may be cited as the "Strengthening Public-safety and Enhancing Communications Through Reform, Utilization, and Modernization Act" or the "SPECTRUM Act".~~

~~**SEC. 2. SENSE OF CONGRESS.**~~

~~It is the sense of Congress that Congress should enact, and the President should sign, bipartisan legislation to strengthen public safety and to enhance wireless communications by—~~

~~(1) providing sufficient wireless spectrum and other resources to build a nationwide interoperable wireless public safety broadband network;~~

~~(2) encouraging more efficient, flexible, and effective use of spectrum, a valuable and finite public resource;~~

~~(3) promoting voluntary market mechanisms to ensure the optimal allocation of spectrum;~~

~~(4) reforming the Federal Government's spectrum management practices; and~~

~~(5) engaging in advanced research and development into emerging wireless technologies.~~

SECTION 1. SHORT TITLE; TABLE OF CONTENTS.

(a) SHORT TITLE.—This Act may be cited as the "Public Safety Spectrum and Wireless Innovation Act".

(b) TABLE OF CONTENTS.—The table of contents for this Act is as follows:

SEC. 2. DEFINITIONS.

In this Act, the following definitions shall apply:

(1) 700 MHZ BAND.—The term "700 MHz band" means the portion of the electromagnetic spectrum between the frequencies from 698 megahertz to 806 megahertz.

(2) 700 MHZ D BLOCK SPECTRUM.—The term "700 MHz D block spectrum" means the portion of

the electromagnetic spectrum between the frequencies from 758 megahertz to 763 megahertz and between the frequencies from 788 megahertz to 793 megahertz.

(3) APPROPRIATE COMMITTEES OF CONGRESS.—Except as otherwise specifically provided, the term "appropriate committees of Congress" means—

(A) the Committee on Commerce, Science, and Transportation of the Senate; and

(B) the Committee on Energy and Commerce of the House of Representatives.

(4) ASSISTANT SECRETARY.—The term "Assistant Secretary" means the Assistant Secretary of Commerce for Communications and Information.

(5) COMMISSION.—The term "Commission" means the Federal Communications Commission.

(6) CORPORATION.—The term "Corporation" means the Public Safety Broadband Corporation established under subtitle A of title II.

(7) EXISTING PUBLIC SAFETY BROADBAND SPECTRUM.—The term "existing public safety broadband spectrum" means the portion of the electromagnetic spectrum between the frequencies—

(A) from 763 megahertz to 768 megahertz;

(B) from 793 megahertz to 798 megahertz;

(C) from 768 megahertz to 769 megahertz; and

(D) from 798 megahertz to 799 megahertz.

(8) FEDERAL ENTITY.—The term "Federal entity" has the same meaning as in section 113(i) of the National Telecommunications and Information Administration Organization Act (47 U.S.C. 923(i)).

(9) NARROWBAND SPECTRUM.—The term "narrowband spectrum" means the portion of the electromagnetic spectrum between the frequencies from 769 megahertz to 775 megahertz and between the frequencies from 799 megahertz to 805 megahertz.

(10) NIST.—The term "NIST" means the National Institute of Standards and Technology.

(11) NTIA.—The term "NTIA" means the National Telecommunications and Information Administration.

(12) PUBLIC SAFETY ENTITY.—The term "public safety entity" means an entity that provides public safety services.

(13) PUBLIC SAFETY SERVICES.—The term "public safety services"—

(A) has the meaning given the term in section 337(f) of the Communications Act of 1934 (47 U.S.C. 337(f)); and

(B) includes services provided by emergency response providers, as that term is defined in section 2 of the Homeland Security Act of 2002 (6 U.S.C. 101).

TITLE I—REALLOCATION OF PUBLIC SAFETY SPECTRUM

SEC. 101. REALLOCATION OF D BLOCK TO PUBLIC SAFETY.

(a) IN GENERAL.—The Commission shall reallocate the 700 MHz D block spectrum for use by public safety entities in accordance with the provisions of this Act.

(b) SPECTRUM ALLOCATION.—Section 337(a) of the Communications Act of 1934 (47 U.S.C. 337(a)) is amended—

(1) by striking "24" in paragraph (1) and inserting "34"; and

(2) by striking "36" in paragraph (2) and inserting "26".

SEC. 102. FLEXIBLE USE OF NARROWBAND SPECTRUM.

The Commission may allow the narrowband spectrum to be used in a flexible manner, including usage for public safety broadband communications, subject to such technical and interference protection measures as the Commission may require.

TITLE II—GOVERNANCE OF PUBLIC SAFETY SPECTRUM

Subtitle A—Public Safety Broadband Corporation

SEC. 201. SINGLE PUBLIC SAFETY WIRELESS NETWORK LICENSEE.

(a) REALLOCATION AND GRANT OF LICENSE.—Notwithstanding any other provision of law, and subject to the provisions of this Act, the Commission shall reallocate and grant a license to the Public Safety Broadband Corporation established under section 202 for the use of the 700 MHz D block spectrum and existing public safety broadband spectrum.

(b) TERM OF LICENSE.—

(1) INITIAL LICENSE.—The license granted under subsection (a) shall be for an initial term of 10 years from the date of the initial issuance of the license.

(2) RENEWAL OF LICENSE.—Prior to expiration of the term of the initial license granted under subsection (a) or the expiration of any subsequent renewal of such license, the Corporation shall submit to the Commission an application for the renewal of such license. Such renewal application shall demonstrate that, during the preceding license term, the Corporation has met the duties and obligations set

forth under this Act. A renewal license granted under this paragraph shall be for a term of not to exceed 10 years.

(c) FACILITATION OF TRANSITION.—The Commission shall take all actions necessary to facilitate the transition of the existing public safety broadband spectrum to the Public Safety Broadband Corporation established under section 202.

SEC. 202. ESTABLISHMENT OF PUBLIC SAFETY BROADBAND CORPORATION.

(a) ESTABLISHMENT.—There is authorized to be established a private, nonprofit corporation, to be known as the "Public Safety Broadband Corporation", which is neither an agency nor establishment of the United States Government or the District of Columbia Government.

(b) APPLICATION OF PROVISIONS.—The Corporation shall be subject to the provisions of this Act, and, to the extent consistent with this Act, to the District of Columbia Nonprofit Corporation Act (sec. 29–301.01 et seq., D.C. Official Code).

(c) RESIDENCE.—The Corporation shall have its place of business in the District of Columbia and shall be considered, for purposes of venue in civil actions, to be a resident of the District of Columbia.

(d) POWERS UNDER DC ACT.—In order to carry out the duties and activities of the Corporation, the Corporation shall have the usual powers conferred upon a nonprofit corporation by the District of Columbia Nonprofit Corporation Act.

(e) INCORPORATION.—The members of the initial Board of Directors of the Corporation shall serve as incorporators and shall take whatever steps that are necessary to establish the Corporation under the District of Columbia Nonprofit Corporation Act.

SEC. 203. BOARD OF DIRECTORS OF THE CORPORATION.

(a) MEMBERSHIP.—The management of the Corporation shall be vested in a Board of Directors (referred to in this subtitle as the "Board"), which shall consist of the following members:

(1) FEDERAL MEMBERS.—The following individuals, or their respective designees, shall serve as Federal members:

(A) The Secretary of Commerce.

(B) The Secretary of Homeland Security.

(C) The Attorney General of the United States.

(D) The Director of the Office of Management and Budget.

(2) NON-FEDERAL MEMBERS.—

(A) IN GENERAL.—The Secretary of Commerce shall appoint 11 individuals to serve as non-Federal members of the Board.

(B) STATE AND LOCAL INTERESTS TO BE REPRESENTED.—In making appointments under subparagraph (A), the Secretary of Commerce, in consultation with the Secretary of Homeland Security and the Attorney General of the United States, should—

(i) appoint at least 3 individuals to represent the collective interests of the States, localities, tribes, and territories;

(ii) seek to ensure geographic and regional representation of the United States in such appointments; and

(iii) seek to ensure rural and urban representation in such appointments.

(C) PUBLIC SAFETY INTERESTS TO BE REPRESENTED.—In making appointments under subparagraph (A), the Secretary of Commerce should appoint at least 3 individuals who have served or are currently serving as public safety professionals.

(D) REQUIRED QUALIFICATIONS.—

(i) IN GENERAL.—Each non-Federal member appointed under subparagraph (A) should meet at least 1 of the following criteria:

(I) PUBLIC SAFETY EXPERIENCE.—Knowledge and experience in the use of Federal, State, local, or tribal public safety or emergency response.

(II) TECHNICAL EXPERTISE.—Technical expertise and fluency regarding broadband communications, including public safety communications.

(III) NETWORK EXPERTISE.—Expertise in building, deploying, and operating commercial telecommunications networks.

(IV) FINANCIAL EXPERTISE.—Expertise in financing and funding telecommunications networks.

(ii) EXPERTISE TO BE REPRESENTED.—In making appointments under subparagraph (A), the Secretary of Commerce shall appoint—

(I) at least one individual who satisfies the requirement under subclause (II) of clause (i);

(II) at least one individual who satisfies the requirement under subclause (III) of clause (i); and

(III) at least one individual who satisfies the requirement under subclause (IV) of clause (i).

(E) INDEPENDENCE.—

(i) IN GENERAL.—Each non-Federal member of the Board shall be independent and neutral.

(ii) INDEPENDENCE DETERMINATION.—In order to be considered independent for purposes of this subparagraph, a member of the Board—

(I) may not, other than in his or her capacity as a member of the Board or any committee thereof—

(aa) accept any consulting, advisory, or other compensatory fee from the Corporation; or

(bb) be a person associated with the Corporation or with any affiliated company thereof; and

(II) shall be disqualified from any deliberation involving any transaction of the Corporation in which the Board member has a financial interest in the outcome of the transaction.

(F) NOT OFFICERS OR EMPLOYEES.—The non-Federal members of the Board shall not, by reason of such membership, be considered to be officers or employees of the United States Government or of the District of Columbia Government.

(G) CITIZENSHIP.—No individual other than a citizen of the United States may serve as a non-Federal member of the Board.

(b) TERMS OF APPOINTMENT.—

(1) INITIAL APPOINTMENT DEADLINE.—Members of the Board shall be appointed not later than 180 days after the date of the enactment of this Act.

(2) TERMS.—

(A) LENGTH.—

(i) FEDERAL MEMBERS.—Each Federal member of the Board shall serve as a

member of the Board for the life of the Corporation.

(ii) NON-FEDERAL MEMBERS.—The term of office of each non-Federal member of the Board shall be 3 years. No non-Federal member of the Board may serve more than 2 consecutive full 3-year terms.

(B) EXPIRATION OF TERM.—Any member whose term has expired may serve until such member's successor has taken office, or until the end of the calendar year in which such member's term has expired, whichever is earlier.

(C) APPOINTMENT TO FILL VACANCY.—Any non-Federal member appointed to fill a vacancy occurring prior to the expiration of the term for which that member's predecessor was appointed shall be appointed for the remainder of the predecessor's term.

(D) STAGGERED TERMS.—With respect to the initial non-Federal members of the Board—

(i) 4 members shall serve for a term of 3 years;

(ii) 4 members shall serve for a term of 2 years; and

(iii) 3 members shall serve for a term of 1 year.

(3) VACANCIES.—A vacancy in the membership of the Board shall not affect the Board's powers, and shall be filled in the same manner as the original member was appointed.

(c) CHAIR.—

(1) SELECTION.—The Secretary of Commerce shall select, from among the non-Federal members of the Board, an individual to serve for a 2-year term as Chair of the Board.

(2) CONSECUTIVE TERMS.—An individual may not serve for more than 2 consecutive terms as Chair of the Board.

(3) REMOVAL FOR CAUSE.—The Secretary of Commerce may remove the Chair of the Board and any non-Federal member for good cause.

(d) REMOVAL.—All members of the Board may by majority vote—

(1) remove any non-Federal member of the Board from office for conduct determined by the Board to be detrimental to the Board or Corporation; and

(2) request that the Secretary of Commerce exercise his or her authority to remove the Chair of the

Board for conduct determined by the Board to be detrimental to the Board or Corporation.

(e) MEETINGS.—

(1) FREQUENCY.—The Board shall meet in accordance with the bylaws of the Corporation—

(A) at the call of the Chairperson; and

(B) not less frequently than once each quarter.

(2) TRANSPARENCY.—Meetings of the Board, including any committee of the Board, shall be open to the public. The Board may, by majority vote, close any such meeting only for the time necessary to preserve the confidentiality of commercial or financial information that is privileged or confidential, to discuss personnel matters, or to discuss legal matters affecting the Corporation, including pending or potential litigation.

(f) QUORUM.—Eight members of the Board shall constitute a quorum, including at least 6 non-Federal members of the Board.

(g) BYLAWS.—A majority of the members of the Board of Directors may amend the bylaws of the Corporation.

(h) ATTENDANCE.—Members of the Board of Directors may attend meetings of the Corporation and vote in person, via telephone conference, or via video conference.

(i) PROHIBITION ON COMPENSATION.—A member of the Board of the Corporation shall serve without pay, and shall not otherwise benefit, directly or indirectly, as a result of their service to the Corporation, but shall be allowed a per diem allowance for travel expenses, at rates authorized for an employee of an agency under subchapter I of chapter 57 of title 5, United States Code, while away from the home or regular place of business of the member in the performance of the duties of the Corporation.

SEC. 204. OFFICERS, EMPLOYEES, AND COMMITTEES OF THE CORPORATION.

(a) OFFICERS AND EMPLOYEES.—

(1) IN GENERAL.—The Corporation shall have a Chief Executive Officer, and such other officers and employees as may be named and appointed by the Board for terms and at rates of compensation fixed by the Board pursuant to this subsection. The Chief Executive Officer may name and appoint such employees as are necessary. All officers and employees shall serve at the pleasure of the Board.

(2) LIMITATION.—No individual other than a citizen of the United States may be an officer of the Corporation.

(3) NONPOLITICAL NATURE OF APPOINTMENT.—No political test or qualification shall be used in se-

lecting, appointing, promoting, or taking other personnel actions with respect to officers, agents, or employees of the Corporation.

(4) COMPENSATION.—

(A) IN GENERAL.—The Board may hire and fix the compensation of employees hired under this subsection as may be necessary to carry out the purposes of the Corporation.
